Metallurgical & Chemical Engineering

A Semi-monthly Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XVIII

From January 1 to June 15, 1918

---

436 843
3. 7. 45

NEW YORK:
McGRAW-HILL COMPANY, Inc.

INDEX TO VOLUME XVIII

GENERAL ALPHABETICAL INDEX

Entries from the Synopsis of Periodical Literature are indicated by S. (Synopsis); from the Analysis of Current Electrochemical, Chemical and Metallurgical United States Patents by P. (Patents).

A

Abrasives, Production 540
Absorbing process for toluol..... 145
Absorption by colloids..... 516
Acetaldehyde, Manufacture from acetylene. Hibbert. (P.)..... 41
Acetone controlled by the Government.. 370
Acid concentrating, Outlet for. Dye and Lucas. (P.)..... 99
Acids, Effect of on wood..... 528
Acid elevator, Automatic..... 553
Acid, Lactic, Manufacture of. Saxe. (P.)..... 99
Acid liquor, Sulphite. Jenssen. (P.).. 154
Acid, Sulphuric acid situation in U. S. Skinner 82
Acidity, Determination in water, leach liquors, mine waters, etc. Rankin 96
Addition agents for copper electroplating.
—— Hogaboom 508
—— Mathers 508
—— Witherell 510
Addition agents in flotation. Thornberry and Mann.....71, 249
Africa, Iron reserves..... 572
Agitator, For gas producers..... 102
Air drying Moore..... 129
Air Nitrates Corporation..... 506
Alabama, Mineral resources. Smith.... 449
Alabama Power Co..... 472
Alcohol from sulphide pulp and paper liquor. Hendrick 360
Alcohol, Laws bearing on importation of distilled spirits 11

Alcohol, Manufacture. Lacy (P.)..... 209
Allied Purchasing Commission..... 13

ALLOYS:
——Acid-proof. Irmann (S.)..... 261
——Aluminium. McAdams. (P.).... 101
——Bibliography of Estes..... 312
——Chromium. Becket. (P.)..... 208
——Cobalt, Chromium tungsten and molybdenum. Haynes 541
——Determination of temperatures by eutectics. Stienmetz (S.)..... 207
——Iron-Cobalt. Becket (P.)..... 208
——Magnesium aluminum..... 285
——Stellite Haynes..... 541
——Thermoelectric force of. Hunter and Bacon..... 512
——Tungsten. Goldschmidt and Weil. (P.) 208
Alternating-current electrolysis. Weiser (S.) 548
Alum from clay. Jackson. (P.)..... 316
Aluminium, Alloy. McAdams. (P.)... 101
Aluminum Co. of America, Power development 502
Aluminium. Metallography of. Anderson 172
Aluminium sheet, Annealing and recrystallization of cold-rolled. Anderson..... 523
Aluminium, Value of 1917 production.. 307
Alunite, Potassium sulphate from..... 391
Amalgamation and cyaniding. Allen.... 515
American Ceramic Society, New York State Branch..... 28

AMERICAN CHEMICAL SOCIETY:
——Delaware section meeting..... 287
——New York Section meetings...171, 289
——Officers 210
American electrochemical industry, Future of. Maher..... 513

AMER. ELECTROCHEMICAL SOCIETY:
——New York Section meetings... 171, 289
——Southern convention..... 500
——Spring meeting 231
——Spring meeting and Southern trip, with map 335
American Engineering Service Committee 231
American Institute of Chemical Engineers:
——Presidential address. Thompson... 21

AMER. INSTITUTE OF MINING ENGINEERS:
——Expell enemy aliens..... 651
——N. Y. Section:
—— Annual meeting..... 571
—— Meeting 394
—— Program 63
—— Report 227
——Summer meeting 575

American Iron and Steel Institute:
——Meeting 531
——New York meeting..... 628
American Smelting & Refining Co. vs. Bunker Hill and Sullivan..... 443
American Society for Testing Materials:
——Annual meeting 569
Ammonia and cyanide. Starke. (P.).... 423

AMMONIA:
——Demand for munitions..... 298
——License required to handle..... 64
——Oxidation and synthetic process in Great Britain 77
——Physical constants of. Osborne and Van Dusen. (S.)..... 653
——Recovery from gas. Unger. (S.).. 373
——Recoveries from tar. Woodward... 299
Ammonia refrigeration in munitions. Morey 389
—— Williams 390
Ammonium nitrate manufacture. Blom. (P.) 423
Ammonium nitrate, New cyanamid plant to make. 1
Anaconda Copper Mining Company, Producing ferromanganese..... 391
Anaconda, Pinedale mine at. Wiggin. (S.) 653
Anaconda, smoke purification..... 392

ANALYSIS:
——Acidity in water, leach liquors, etc. Rankin. 96
——Carbon, Jackson. 564
——Ferrosilicon. Mammen. 438
——Ferrosilicon. Anger. 512
——Ferrosilicon. Anger. (S.)..... 610
——Natural gas..... 640
——Phosphorus in high-speed steels. Sheffield and van Valkenburgh (S.) 61
——Sulphur burner gases. Williams. (S.) 314
——Titanium in ferrotitanium. Roehl. (S.) 38
Annealing and recrystallization of cold-rolled aluminum sheet. Anderson. 523
Anode, Arrating. Hanley. (P.)..... 484
Anode, Method of suspension. Antisell. (P.) 375
Antimony, Russian production..... 370
Antimony Tariff Commission conference. 644
Appalachian South, Mineral resources.. 449
Arizona copper mill, Increase of mill capacity. 566
Aromatic chlorides by catalysis. Mailhe. (S.) 545
Aromatics, Solubility on liquid sulphur dioxide. Moore, Morrell and Egloff 396
Arsenic smelter by-product..... 284
Ashes, Electric hoists for..... 486
Australia, Proposed iron and steel works for Queensland..... 519
Automatic furnace control..... 488

B

Baily electric furnace..... 156
Ball-milling Theory and practice of peripheral discharge Hines.. 229
Ball-mill crushing at Inspiration Miami and Anaconda Kennard (S.). 653
——Wiggin (S.)..... 653
Ball mill tests at Inspiration. Van Winkle. (S.) 207
——Channing 228
——Gottschalk 229
Barium sulphide. Prisk and Harrison. (P.) 423
Belt slip, Cost of..... 426
Benzine-naphthalene dyes. Grünhagen. (P.) 373
Benzol, As motor fuel in England. Clegg. (S.) 39
Benzol, Purification of crude. Kipper. (P.) 210
Benzol-recovery plant operation. Laboratory methods for Sperr. ... 169
Bibliography, Physical properties of copper. Merica 408
Bismuth, Chemically pure. Mylius and Groschuff. (S.)..... 38
Bismuth, Russian production..... 370
Bismuth, Smelter by-product 284
Blast furnace flue dust, Sintering. Boyntun and Sands. (P.)..... 662
——Dwight Lloyd 319

Blast furnace gas, Potash from. Leigh. S.) 429
——Chance 420
Blast furnaces, Potash from. Berry and McArthur. (S.)..... 547
Blast-furnace slags, Viscosity. Feild. (S.) 652
Boiler plates, Fatigue failure. Wolff. (S.) 313
Bombardment, Paris, Long-Range. Tomlin. 622
Bone-ash cupels. Dewey. 228, 260
Bonus systems..... 241

BOOK REVIEWS:
——Battle, Lubricating Engineers' Handbook 489
——Blaisdale, Principles of Quantitative Analysis..... 266
——Berry, Eye Hazards in Industrial Occupations 489
——Bullens, Steel and its Heat Treatment 657
——Ferry, Shook and Collins, Practical Pyrometry 45
——Finding and Stopping Waste in Modern Boiler Rooms..... 213
——Getman, Standard Table of Electrochemical Equivalents and Their Derivatives, With Explanatory Text 321
——Hendrick, Everyman's Chemistry.. 46
——Hering, Standard Table of Electrochemical Equivalents and Their Derivatives, With Explanatory Text 321
——Herington, R. Powdered Coal as a Fuel..... 657
——Kover and Hanson, Diseases of Occupation and Vocational Hygiene. 657
——Loff and Rushmore, Hydro-Electric Power Stations..... 489
——Lunge, Coal-Tar and Ammonia.... 213
——Lunge, Sulphuric Acid and Alkali 214
——Meade, The Technical Analysis of Brass and Non-Ferrous Alloys.. 266
——Mellor, Modern Inorganic Chemistry 554
——Methods for the Technical Sampling and Analysis of Gases..... 657
——Report of the Royal Ontario Nickel Commission 322
——Richards, Metallurgical Calculations. Part I, Revised..... 45
——Richards, J. W. Metallurgical Calculations..... 657
——Rodenhauser and Schoenawa, Electric Furnaces in the Iron and Steel Industry..... 489
——Rogers, Laboratory Guide of Industrial Chemistry..... 46
——Scott, The Journal of the Institute of Metals..... 489
——Smith, Life of Robert Hare..... 213
——Steinmetz Theory and Calculation of Electric Circuits..... 266
——Steinmetz Theory and Calculations of Electrical Apparatus .. 267
——Fahrenwald, Testing for a Flotation Process 213
——Thun, A Practice Book in Elementary Metallurgy..... 46
——Villavecchia, Treatise on Applied Analytical Chemistry 488
——Wagner, Coal Gas Residuals..... 554
Booth-Hall electric steel furnace..... 211
Brass, Electric furnace for melting Gillett and Rhoads 583
Brass furnaces in commercial use..... 584
Brass melting Johnson. (P.) 315
Brass special spelter..... 135
Brazil, Iron resources..... 571
Brick, Chrome Disadvantages in copper reverberatory furnaces .. 20
——Dolomite refractory Handy and Isham. (P.)..... 42
——Fire, Palmerton refractories. Fiske. (S.) 97
——Nonpareil, Insulation test on steam drums 44
——Refractory Furnace for testing. Montgomery 18
Briquetting machines, Scrap metal .. 157
British Nitrogen Products Committee, Work of 77
British non-ferrous metal industry act .. 580
Bucket elevator, Hints on operation. Nichols 229
Bully Hill Copper Mining & Smelting Co. Electrolytic zinc. (P.)..... 485
Bunker Hill suit ended..... 443
Bureau of Mines, Seattle station..... 625
Burner, Fuel oil 156

Butte & Superior vs. Mineral Separation 570
By-product coke, Development in, Walker (S.) 371

C

Cadmium, Removal from zinc ore. Fiske. (P.) 551
Cadmium, Smelter by-product 284
California kelp operations of the Hercules Powder Co. 576
California, Electrochemistry and metallurgy in. 624
——Platinum from placer 392
California Railway Commission 624
Calumet & Arizona Mining Co., Annual report. 627
Canada, Advances in metallurgy. Stansfield. (S.) 481
——Electric furnaces in 317
——Metal production in 1917 61
Canadian lead situation 283
Canadian mineral production 624
Canadian Mining Institute, Montreal meeting 337
Canadinm, Composion of 81
Cane sugar, Decomposition point 301
Canning compounds. Schmidt and Andres. (P.) 317
Capital and labor, Important developments relating to. 393
Carbon cell, Experiment. Reed. 512. (S.) 610
Carbon dioxide, Determination of loss due to low 551
Carbon, Rapid determination. Jackson 564
Car loader, Portable 157
Carolina Light & Power Co. 472
Catalysis, Aromatic nitriles. Mailhe. (S.) 545
Catalysis, Dimethylaniline. (S.) 545
Catalyzer, Oleates catalytic catalysts. Ellis. (P.) 208
Causticizing soda ash with lime, Continuous process 376
Causticizing soda liquors. Goodner 169
Caustic liquors, Action on steel. Stromeyer, Worsfe. (S.) 372
Caustic soda, Production. Bradley. (P.) 99
Celite, Use in filtration 101
Cell, Experimental carbon. Reed. 512. (S.) 610
Celluloid, Effects of heat on. Stokes and Weber. (S.) 38
Celluloid incombustible 446
Cement, Potash from. Anderson. (P.) 99
Cement, Potassium sulphate from 391
Central station and electrochemical products. Winder 354
Central stations and electrochemistry. St. John 621
Ceramics and the war. Washburn 253
Cercle de la Chimie 81
Charcoal precipitation of aurocyanide. Allen 642
Chemical Alliance, Inc. 120
——First annual meeting 171
——Formation 95
Chemical apparatus, Wood for. Schorger 528
Chemical companies, The need for organization for new. Hemingway. 180
Chemical market, Review of 1917 46
Chemical industries in the Southern States. Meade 466
Chemical market and price list. 51 106. 158. 215. 268. 323. 379. 428. 491. 556. 612
Chemical drying. Moore 131
Chemical Trade specification 479
Chemistry and the war. Jackson 168
Chemistry in the petroleum industry. Burton 647
Chief metal testing. Erichsen. (P.) 263
Chihuahua smelter reopened 607
Chile, Potash from nitrate 248
Chimie & Industrie 252
China, Iron reserves 572
Chlorides, Effect on flotation ores. Thornberry and Mann 249
Chloridizing spent pyrite. Sutcliffe. (P.) 262
Chlorination of pitchblende for radium. Cable and Schlundt 460
Chlorine products from. Kipper. (P.) 374
Chlorine, Products from hydrocarbons. Blanc. (P.) 100
Chromium. (See Stellite)
Chlorine, Toluol derivatives. Gibbs. (P.) 100
Chrome brick Disadvantages in copper reverberatory furnaces. Pyne. 228
Chromite and Kaolinite, Freezing point curves. Hofman 228
Clay, Alum from. Jackson. (P.) 316
Clay, American, For graphite crucibles. 265

COAL:

——Carbonization, Illinois, Ovitz. (S.) 548
——Distillation. Foxwell. (P.) 374
——Power from 61
——Suggestions for conservation 12
Coal-washing, Use of culm and other waste materials. Kershaw 25
Cobalt. (See stellite)
Coke By-product plant, Colorado Fuel & Iron Co. 567
Coke Developments in by-products. Walker. (S.) 371
Coke, Hydrocarbon. Perry (P.) 423
Coke-oven gas measurement for soaking pits. 425
Coleman oil burner 156
Colorado Fuel and Iroo Co. By-product coke plant 567
Colorado Scientific Society, Officers for 1918. 81
Colorado, Smelter and Ore Sales Investigation. 365
——Report 284
Colorado smelter, By-products from 284
Columbus Power Co. 473
Combustion, Loss due to low-carbon dioxide. 551
Competition, Factors in world trade 224
Composition of rail steel, Cram. (S.) 313
Concentration, Burro-Mountain concentrator. 8
Concentrates, Analysis by microscope. Thomas and Apgar 514
Consolidated Arizona Smelting Co., Annual report 626
Conversion table, pounds to grams. Gerber. 60

COPPER:

——Alloys with nickel and tungsten. Irmann. (S.) 261
——Concentration, Burro Mountain concentrator. 8
——Comparison of nitric acid and leaching processes. 293
——Copper-lead smelter schedule 367
——Corrosion of 359
——Determination, Ammonia method 203
——Determination, Sodium tartrate 203
——Determination, Sulphuric acid method. 203
——Determining minerals in partly oxidized ores. Cremer 644
——Diseases of 359
——Effect of boiling sulphur on. Hayward. 650
——Effect of heat-treatment on physical properties. 303
——Effect of impurities on physical properties. 303, 357
——Effect of, in steel. Heyward and Johnston. 260
——Electrolysis of foul sulphate. Antisell. (P.) 423
——Electrolytic, Effect of iron sulphate. Kern. 507
——Electroplating baths. Mathers 508
——Metallurgy in 1917 4
——Minerals, sulphur dioxide method for determining in partly oxidized ores. Van Barneveld and Leaver. 203
——Nickel-copper separation. Guess. (P.) 424
——Nitric acid process for. Westby 290
——Physical Properties of, The factors by which they are Affected. Merica. 121, 192, 303, 357, 409
——Refining, Disadvantages of chrome brick in reverberatory furnaces. 20
——Reverberatory furnaces, Disadvantages of chrome brick in. Pyne. 228
——Separation of, during concentration of matte. Stahl (S.) 313
——Sulphur dioxide method for analysis of partly oxidized ores, van Barneveld. 390
——Smelting, Reverberatory construction at Hayden plant of A. S. & R. Co. 8
Corrosion: 264
——Parket rust-proofing process 510
——Rusting of rails. Watts
Côte and Pierron electric zinc-smelting process. 17
Cottrell system, Smoke purification at Anaconda. 392
Council of National Defence:
——Industrial Service Section 13
——Reorgaoized. 12
Culm, Use of. Kershaw 25
Cuba, Iron reserves 572
Cupels, Bone-ash. Dewey 228, 260
Current control, Seede. (P.) 315
Cyanamide, Sem. (P.) 423
Cyanamide manufacture in Great Britain 77
Cyanamide plant at Muscle Shoals 1
Cyanide and ammonia, Starke. (P.) 423
Cyanide, Chemical and mechanical loss 517
Cyanide mill schedule 366
Cyanide solution, Milling in. Allen 515

D

Dayton Engineers Club, New home 63
Depolarization by sulphur dioxide, Thompsoo and Sullvan 178
Dextrose, Decomposition point 301
Dilatometer, a Gas, Monre and Davies. 301
Dimethylaniline by catalytic dehydration, Mailhe and de Godon. (S.) 545
Distillatioo, Dry, Experimental retort for. Coombs 425
Dorrite insulating material 103
Drying and evaporation, Some problems in. Sadtler and de Beers 543
Drying, General aspects, Moore 128, 186
du Pont Co. vs. Walter Masland 64
Dyes, Sulphur, Heinmann. (P.) 155
Dyestuff Association, Organized 120, 479

DYESTUFFS:

——Beta-naphthol benzoate. Blieberger. (P.) 373
——Blueish-green vat dyes. Kardos and Narviasky. (P.) 209
——Manufacturers organization 289
——Phthalic anhydride. Greenley. (P.) 484

DYESTUFFS—*Continued:*

——Vat dyestuffs, Schmidt. (P.) 483
—— Iljinsky. (P.) 484

Filtration, Basalt lava for..... 373
Filtration, Developments in, Jordan.. 101
——Plate-and-frame, Sperry..... 258
Fire foam..... 486
Fire protection for chemicals and oils.. 486
Fish oil, deodorizing..... 608
Flotation litigation. (See Minerals Separation.)

FLOTATION:

——Early practice of, Thomas..... 565
——Effect of addition agents, Thornberry and Mann 71, 249
——Groch machine, Groch and Simpson. (S.) 373
——In gold and silver metallurgy..... 2
——Machine, Fahrenwald 487
——Molecular physics of, Coghill and Anderson. 595
——Review of 1917 practice..... 5
——Selective, At Eureka, Colo..... 170
Fractures, Fatigue, in steel rails, Howard. 230
French Chemists' Club..... 81
Fuel oil now under licenses..... 178

Furnace: Blast, Volume regulator for engines, Loewenstein..... 29
Furnace control by optical pyrometers, Fenner. (S.) 481
——Application to industrial processes. Etchells. 480
—— Greaves-Etchells. 480
—— Steel refining, Bibby. 480

FURNACE CONTROL—*Continued.*

——Automatic control..... 488
——Daily automatic heat-treating..... 156
——Booth. (P.)..... 315

FURNACE, ELECTRIC:

——Booth-Hall electric 211, 510
——Bureau of Mines..... 583
——Dickson. (P.) 263
——Distribution of, Canada..... 317
——For standardizing thermocouples... 347
——Fractionating hydrocarbons. Hirt. (P.) 98
——Fulton's zinc..... 539
——Funck. (P.)..... 315
——Furnace control. Cleming and Hill 480
——High-temperature tuagsten or molybdenum resistance. Ruder.... 228
——Induction. Wyatt. (P.)..... 374
——Johnson. (P.)..... 315
——Log of tool steel furnace. Suverkrop (S.) 371
——Nitrogen fixation. Scott..... 504
——Price. (P.)..... 315
——Rocking, for brass. Gillett and Rhoads. 583
——Seede. (P.)..... 316
——Sperling. (P.)..... 315
——Steel turnings for..... 372
——Valentine. (P.)..... 315
——Vom Baur. (P.) 263, 510
——Water-cooled linings. Price. (P.)... 315
Furnace, Reverberatory, Disadvantages of chrome brick 20
Furnace Testing, For refractory materials, Montgomery..... 18

G

Gas, Analysis of natural..... 640
Gas attacks, Defensive measures against, Tomlin. 636

Important Developments in Nitrogen Fixation

IT is now apparent that our requirements of ammonia and nitrates to be used in the manufacture of explosives for our army and navy have been greatly underestimated, and that the gravity of the situation which has been slowly but surely approaching has not been realized by the majority of the Government's advisers.

Important developments have recently taken place. In spite of the fact that our imports of Chile nitrate have increased enormously during the last two years—and our production of by-product coke ammonia has also increased to an enormous extent—the Government finds itself facing a serious shortage of ammonium nitrate. The Ordnance Department has consequently appointed the Air Nitrates Corporation its agent to construct and operate an immense plant at Muscle Shoals, Ala., to manufacture ammonium nitrate by the cyanamid nitrogen-fixation process. The arrangement is unique in Government affairs. The officers of the new company are at the head of the American Cyanamid Company and the services of that company's entire organization have been patriotically offered to the Government in connection with the project. Work is already under way on this new plant, which is entirely independent of the small plant now being built at Sheffield, Ala., to use the synthetic ammonia process recommended early in the fall by the Nitrate Supply Committee. Power will be obtained from the Alabama Power Company, pending the completion of the power plant, which is part of the hydroelectric development. In the meantime about 30,000 horse power will be supplied from the hydroelectric plant of the Alabama Power Company and 30,000 more from a steam plant now being constructed. Shipments are expected from the plant in six months.

It will be remembered that Congress appropriated $20,000,000 in June, 1916, for nitrate supply. A Nitrate Supply Committee was later appointed by the Secretary of War to investigate various sources and processes of production of nitrates and nitric acid. We published the final recommendations of this committee a few months ago. They were, in brief, that a 30-ton per day synthetic ammonia plant should be constructed to use the General Chemical Company process and that an ammonia oxidation plant be constructed to produce 12 tons of nitric acid per day. Appropriations were also recommended for experimentation with other processes

and it was recommended that 500,000 tons of Chile nitrate be accumulated as a reserve. Following these recommendations work was started on the synthetic ammonia plant, and is understood to be at present in progress. It is plainly evident now, however, that this source of supply in its present stage is not considered a very large factor by the War Department.

In studying the Nitrate Supply Committee recommendations one gets the impression very clearly that we had no urgent needs for nitrogen fixation, as considerable experimentation and development work was provided for and only $3,600,000 out of the $20,000,000 was to be spent at once in building plants for producing 10,000 tons per year of ammonia and about 4,000 tons per year of nitric acid. The cyanamid process was not mentioned in the final recommendations.

It will be remembered that Mr. Washburn, president of the American Cyanamid Company, offered in 1915 to build a $30,000,000 plant on a suitable water-power site to make nitric acid for war needs and fertilizer in peace times. He had been requested by the War Department to present a scheme for nitrogen supply, and his ideas were published by us in April, 1916. Muscle Shoals was considered by many the ideal site for such a plant, and this dream is shortly to be realized. It was also very clearly brought out by Mr. Washburn that coke-oven ammonia could not be depended on to furnish us with ammonia for making nitric acid and nitrates in case of war. He showed that this ammonia was completely consumed in industries from which it could hardly be withdrawn without great damage in case of war (37 per cent is used in cold storage, 10 per cent in explosives and chemicals and the balance in fertilizers). We quote Mr. Washburn as follows:

> Germany, the greatest European country in metallurgical industry, producing 90 per cent of her coke supply in by-product plants, turned to atmospheric nitrogen for her war requirements. . .
>
> One of the serious limitations upon the growth of the by-product coke oven is the relatively great investment involved therein. ($100,000,000 required to produce ammonia sufficient to make 180,000 tons of nitric acid per annum.) Notwithstanding these facts some enthusiasts have suggested that coke ovens could be erected wholesale in times of war.

These developments bring out two facts. First, that our needs have been greatly underestimated by the majority, and second, that in time of war quick action is needed and no time can be lost in experimentation or indulging in fascinating possibilities. The Government's decision does not discredit in the least the General Chemical Company's process nor the excellent work done by the Nitrate Supply Committee. It appears, however, that they greatly underestimated our needs and the necessity for quick action, and failed to recommend the use of the "bird in the hand," the cyanamid process, which had been thoroughly proved on an immense scale and was already well understood by American engineers. The reader is referred to Nauchkoff's article in our issue of Nov. 1, 1917, which shows the nitrogen resources of the warring nations very clearly and the part the cyanamid process plays.

It may be perfectly true that the synthetic ammonia process with subsequent oxidation of the ammonia to nitric acid would be the most desirable from several standpoints in the long run, but many large-scale problems have yet to be met, and we have no time to wait. If the war continues any length of time we can use more than the output of both the synthetic ammonia and the cyanamid plants. Mr. Washburn estimated in 1916 that a plant such as is now being built at Muscle Shoals would produce the equivalent of 180,000 tons of nitric acid per year. We are not permitted at present to go into further details as to the Government's needs and the new plant, but we have very good reasons to believe that even this plant will be inadequate to meet our needs in a short time, so rapidly are they increasing.

Review of Gold and Silver Metallurgy

IT is now a year since we commented on the anomalous position of the gold producer in this era of advancing prices. More recent events have accentuated these conditions; doubly so, perhaps, because long-delayed prosperity came to the relief of the silver miner.

The high commodity prices and acute labor shortage prevalent throughout the world have borne heavily upon the gold miner, who, unable to recoup his expenditures by advancing the price of his own wares, has been at a disadvantage in competing in the labor market. Similar conditions are reflected in all our news from abroad, and Canada, Australia and South Africa are alike suffering from an insufficient supply of labor. T. T. Read recently summarized the situation in a pleasing phrase to the effect that we have passed from the position of buying labor to selling employment.

In such circumstances it is but natural that the past year has been marked by a singular lack of activity in the development of new processes and the erection of new plants. In general, it may be said that the metallurgist's attention has been engaged by collateral lines of activity rather than by those directly affecting his specialty, but always with their extension and future application in mind.

Thus his interest in grinding machinery and in flotation has continued. In a measure he has accepted the ball mill as standard practice, if we may so interpret the new mills at Oatman and the remodeling of the Dome plant. Parenthetically, it may be noted that ball mills crushing in cyanide solution and followed by fine-grinding machinery, Dorr counter-current decantation and Merrill precipitation equipment, constitute the modern plant. This flow-sheet indicates the discarding of amalgamation, and in such circumstances at least the ball mill seems to be the logical machine. Where amalgamation is to be retained in the scheme of treatment the matter is not so clear, since the "inside amalgamation" of the stamp mill cannot well be supplied to the ball mill by reason of difficulties of clean-up. It is our impression, however, that this objection need not be of serious import, since this "inside amalgamation" tends primarily, by its vigorous churning or mixing of quicksilver and pulp, to collect and amalgamate the extremely fine gold particles in the "slime" portion of the ore—the very particles that may be expected to yield most readily to secondary treatment.

There have been no radical changes in the mechanical equipment of the latest mills; the machines commonly in use for classifying and dewatering are, however, undergoing constant refinement. It is rather interesting to note that whereas mechanical classification is gradually supplanting hydraudic classification in gold and silver milling, a new design of cone, apparently a distant relative of the diaphragm cone of South African practice, is enjoying a certain popularity in the copper districts of the Southwest.

Extreme simplification of the flow-sheet may be leading us to unnecessarily fine grinding: separate treatment of sand and slime is no doubt more often justified than practised.

Flotation has progressed during the year, and in the direction indicated by an examination of its nature and limitations. At Cobalt and in the San Juan it has been of great value. It finds its best opportunity where, in addition to gold and silver, the ore contains sulphides or similar base-metal minerals in commercial quantity; it is least likely to win favor when its product must compete with high-grade bullion, salable to the government without discount. A chapter in Rickard and Ralston's recent book makes an interesting presentation of this phase of the process.

The method of cyanide production proposed by Bucher has attracted much attention. This process, it will be recalled, depends upon the reaction between carbon, sodium carbonate and nitrogen, at a temperature of 900 to 1000 deg. C., using finely divided metallic iron as a catalyzer. Clevenger has suggested what was no doubt in the minds of many others interested in gold extraction—that the cyanide so formed could be taken up at once in works solutions, thus obviating all concentration of the extract.

Bucher's process, unlike another chemical proposition which, a few years ago, gained much publicity in the technical press, lends itself to verification in the hands of others than its inventor. It makes cyanide, and the cyanide it makes, obtained in solution as Clevenger proposes, will extract gold.

Upon examination, it must be confessed that the proposed application loses some of its appeal. Certainly it would be a comfort to have a supply of cyanide always at command, but many an already overburdened millman might well demur to the assuming of one more duty. However this may be, we look for cheaper cyanide in the future, and we hope to see it offered by several new American manufacturers.

Indeed, the general development of America's chemical industries promises excellent things for the future. Zinc dust is now made at several American plants, production no doubt being stimulated by the prevailing prices, which have been firmer than the spelter market would seem to have warranted. The quality of some of these brands is most excellent, and it seems improbable that the German dust will ever command its earlier favor.

Simultaneously with improvement of the precipitant, the technique of precipitation has been refined and developed. The former limitations of the process have undoubtedly been widened. Greater efficiency has been obtained and consequently a higher grade product is now the rule.

Zinc-dust precipitation was already dominant in this country. It will be interesting to observe whether the method will eventually replace the zinc-shaving process from its great stronghold in South Africa. It is conceivable that the sum of several minor improvements such as we have mentioned may finally throw the scale.

The many recent advances in the metallurgy of zinc are of especial interest to the cyanider, who requires the metal in his operations and must perforce tolerate it in his precipitates. In addition to the development of precipitation methods, we may see a revival of the proposal made some ten years ago—to distill the zinc from the precipitates, recovering it for further use.

It seems inevitable that improvements tending to increase the precious-metal content of precipitates will favor the introduction of the electric furnace for refining.

Metallurgy of Zinc in 1917

IT may be said that as zinc was the first metal to be affected by the war boom in metals, so it has been the first to be affected by the deflation consequent upon overproduction, and decrease of consumption due to artificially high prices. The end of the year 1916 saw a marked tendency in this direction. Production was even then already outstripping consumption, and profits were showing a corresponding depreciation. During 1917 the increasing cost of coal and gas fuel, together with the relatively higher cost of ore, has forced such a curtailment of output that at the end of this year we have a condition where only those plants having by-products of value, such as sulphuric acid, can show what even in pre-war days would have been considered a fair profit.

These remarks concerning commercial conditions are made only to call attention to the principal reason for what is apparently a lack of progress in zinc metallurgy during 1917. At a time when the less profitable plants are being shut down and when even the best plants are being forced to pass dividends, it is hardly to be expected that much new capital would be invested in improvements other than those absolutely necessary to meet the increased competition of the time.

The period of exorbitant profits during 1915 and 1916 has not been without its advantages, aside from the large returns paid by most of the smelting companies. New plants were constructed and older ones were enlarged and improved, and these improvements, in regions other than the gas belt, have been of such a character as the industry had not hitherto witnessed. In fact, most of the construction east of the Mississippi River is now such as to give great hopes for a commercially sounder basis for the industry, besides assuring relatively lower costs of production and better recoveries upon a return of normal conditions for labor and supplies.

As the year 1917 brought curtailment of smelter ca-

pacity instead of the expansion to which we had become accustomed, and brought even greater curtailment of profits to most of the smelting companies, so, as might be expected, improvements in the art have not been marked. Attempts have necessarily been made to meet higher labor costs with mechanical devices to increase the tonnage handled per man, and in minor items this has been more or less successfully accomplished.

Outside of the gas fields of Oklahoma and Kansas, practically all zinc sulphide ores are roasted with a special view to the conversion of the sulphur gas to sulphuric acid. For this purpose the roasting furnaces used in American practice have been almost invariably of the Hegeler type. Attempts have been made to introduce furnaces of the Spirlet or of the Wedge type, and such furnaces are, in some cases, in actual operation, but as yet there is no evidence of a desire on the part of operators in general to abandon the better established apparatus.

In the actual operation of the retort furnaces it would seem that there might be much room for labor-saving devices, especially in view of the increased cost of labor. In a few isolated cases mechanical devices for discharging and recharging the retorts are actually in use, and the operators of such devices seem pleased with the results obtained. But again it is to be noted that notwithstanding the present most favorable conditions their use is still confined to a very few plants, and most zinc metallurgists continue to look upon them as interesting experiments which may some day be worth investigating.

The metallurgy of zinc, as practised today in the older retort process, has been of slow growth, and is the result of many years' accumulated experience. The financial path of zinc metallurgy may be said to be marked by the tombstones of defunct processes. It has only been of recent years, especially since the metallurgist has been confronted by the necessity of smelting lower grade and more complex ores, that there have been any encouraging signs that new conditions might bring out new methods to meet them. The necessity for handling complex ores, low in zinc, especially those common in the Rocky Mountains, coupled with the abnormal demands for spelter of a great degree of purity which has accompanied the war conditions, has given the opportunity for the development of an entirely new process in zinc metallurgy.

Previous to the present year the production of electrolytic zinc had been measured in a few tons per day, and had taken place mostly on an experimental scale. During this year, however, the production of zinc by electrolysis may be said to have passed from the experimental to the commercial basis. The longest step taken, of course, has been that at Great Falls, although a number of other plants have come in with tonnages which, while much inferior to the output of Great Falls, are, nevertheless, of considerable magnitude.

It is, perhaps, too early yet to say just in what direction this new art will work out to the greatest advantage. The operations at Great Falls involve wet concentration of the ore to a high-grade product, followed by roasting and leaching of the concentrate. This results in a residue containing a considerable amount of zinc, and attempts have been made to smelt this material in a reverberatory furnace, whereby the zinc is volatilized and a commercial quantity of the other metals collected in the form of a copper matte.

The work now being done on Colorado ores by another company, having an electrolytic refinery at Keokuk, Iowa, is carried out on lower grade and more complex ores. These are partly roasted, then smelted directly in a reverberatory furnace. By this means the lead and zinc are separated in a relatively pure form from the gangue of the ore, and the other metals are concentrated in a matte. The zinc and lead concentrates are then shipped to the refinery for separation.

The plant at Park City, Utah, follows, in general, the Great Falls practice of roasting and leaching, with the addition of revolving cathodes in the electrolytic tanks. The plant at Mammoth, California is operating on a complex baghouse product produced from the smelting of copper ores. This material has as its principal constituent zinc as sulphate, but has many other metals present, tending further to complicate an otherwise not simple process. The successful working out of this problem will reflect much credit on the men in technical charge of the work.

Direct electrothermal smelting of zinc ores seemed at one time to be approaching success. Much interesting and more or less successful work along this line was carried out at Hartford, Conn., a few years ago, but thus far the process has not come into commercial use. A plant is now being built by the Guggheim interests at Pueblo, Col. In Norway, plants have been operating some years on such a method, but there the cost of power is lower than anything we have or are likely to have in this country.

Copper Metallurgy in 1917

"GET the Copper" has been the slogan of the producers during 1917. During the first part of the year there seemed to be an unlimited market at very fancy prices—published quotations for spot metal ranged from 29 to 37 cents, then falling back to 25½ cents while the price-fixing program was awaited. Considerable copper changed hands at these figures, even though the bulk of the production was absorbed by the Allies at figures substantially lower, down to one large sale to the American government at about 16.7. The spot prices were evidently so excessive that the efforts of the administration were early turned toward fixing a price for the red metal, which was agreed upon Sept. 20, the official price being set at 23½ cents. This is a quite liberal figure, and one calculated to allow even the most unfavorably situated company to produce at a profit, although later many smiles were provoked by the attempts of brokers and other spokesmen to explain the profound riddle, "When is a low-cost producer, and why?"

The high price and scarcity of machinery and construction materials has not halted a universal extension in plant capacity. While only one notable new

smelter is under construction in the Western States—that of the United Verde Extension, building near Jerome, Ariz.—one can hardly mention a plant in that region which is not engaged in a construction program of considerable magnitude preparatory to a larger output of blister. One notable exception to this statement is the Great Falls plant of the Anaconda Copper Mining Company. Before the war broke out this smelter was one of the world's large copper producers. At the present time but little copper is made, and that merely as a by-product of their zinc plant, recently completed.

These efforts toward maximum production have been more than nullified, however, by an epidemic of labor troubles which seemed to infest the copper mines, smelters and refineries. Strikes of various degrees, intensity and duration spread from one location to another, completely paralyzing the activities of whole districts for as long as five months. These differences have now been largely settled—in some cases by a federal commission working apparently on some such theory as this: "The management and men must come together and resume production; the men will not compromise, therefore the management must."

The significant feature in reverberatory smelting is that oil is becoming too rare and valuable to be used as a fuel, and is to be supplanted by powdered coal. This change has already started. Side-charging of fettling or calcine through numerous holes at the skewback is almost universal. An interesting modification of this plan is that devised by Heggie, where manger-like openings through the side walls are constantly heaped with cold charge. This latter idea has brought about a most interesting and important evolution in buckstay construction, in fact, in the entire scheme of "ironing". a furnace.

In the converting department, the 13-ft. x 30-ft. Peirce-Smith converter mentioned in our review of last year, has amply demonstrated its efficiency, and is being installed in several American Smelting & Refining Company plants. This converter is structurally far superior to the smaller styles, and has established some enviable metallurgical records. Only the long-suffering converter crane-man could fully appreciate the clear air in the El Paso converter aisle, where some real hoods fit closely over the mouths of these new converters. Converter capacity has been materially increased by the common use of a silica gun. This device is merely an air-jet blowing a continuous stream of crushed siliceous material through the end of the converter during its operation. This saves the time of converter and crane necessary to charge this material by boat or chute; further, it facilitates uniform operation at a lower temperature, thus increasing the life of the basic lining. Everyone is still talking about that metallurgical nuisance, converter slag, but nothing new has been done about it. Multi-stage turbo-blowers, both of the Ingersoll-Rand and the Rateau-Bottu-Smoot design, are now quite common in power houses, replacing the bulky blowing engines used to compress converter air.

In copper hydrometallurgy, the successful operation of the New Cornelia plant at Ajo, Ariz., is a matter for congratulation to the metallurgists who worked out the possibilities of the process, and the capitalists who financed this new undertaking. A beautiful process and a beautiful plant! There is, however, one unsolved problem in these leaching processes, that is to say, the treatment of that very considerable percentage of solution which must be "bled" from the circulation to prevent undue accumulation of iron and other metallic impurities. At present the copper in the waste Ajo solution is precipitated on iron, but, as compared to the electrolytic room, these dirty vats seem extremely antiquated. In this connection it would be pertinent to point out that the price of iron scrap is steadily rising, while the prophesy that the easy production of sponge iron from concentrates will take first place as a precipitant seems yet to be fulfilled.

The general interest taken by copper metallurgists in their possible by-products is a good omen—even recent investigations on smelter smoke point to its value as an actual fertilizer. The general production of arsenic from flue dust in normal times served only to glut the market, but these plants are now working to capacity. Sulphuric acid plants are becoming so common as to fail to excite much interest. The old-school metallurgist, however, can hardly recognize that corner of the smelter where potash alum, zinc sulphate, zinc chloride or liquid sulphur dioxide is produced by the ton. Some few of the Western plants seem peculiarly well adapted for the production of brass munitions. Large quantities of electrolytic copper and zinc, ample coal and electricity, an energetic staff and adequate labor supply—this is a conjunction of factors, any one of which is becoming rarer in the Eastern States. In stress of war the past objections to this development, such as lack of market and high labor or freight rates, are either becoming less cogent or disappearing altogether. Eventually, of course, the West will absorb enormous quantities of locally-produced metallifactures; the war may easily hasten the establishment of some of these factories close to the point of production. The construction of a rod-mill of considerable dimensions at Great Falls, Montana, seems an earnest of such near-by developments.

Flotation in 1917

THE interest in flotation has now passed its zenith and the process has become too common a thing to attract the interest that it did while young in its application to American conditions. For the past two years the various hydrometallurgical schemes have had to be set aside more or less to allow the full development of flotation before it was deemed safe to proceed with the more expensive hydrometallurgy. Interest is again beginning to center around the hydrometallurgy of copper, zinc and lead, in addition to the revival of older forms of the hydrometallurgy of silver and gold. The copper hydrometallurgists are reputed to have expected flotation to make leaching of copper from low-grade ores unnecessary, and were expecting to devote their

energy to the hydrometallurgy of flotation concentrate. It now seems certain that flotation will not be the complete solution of the treatment of low-grade oxidized copper ores, and that hydrometallurgy will come back to its own.

The various schemes for the flotation of oxidized minerals have been further tested and found wanting, for a number of reasons. In the first place, most of them are very likely to be spoiled by the appearance of ore of a slightly different composition than that for which they had been designed. For instance, it has been found that the oxidized ores of lead which can be sulphidized and floated are few in number, and that the great majority contain materials which consume the sodium or hydrogen sulphide used for sulphidizing. Such things as basic sulphate of iron or manganese dioxide are of common occurrence in oxidized ores, and tend to prevent good sulphidizing. So while there are undoubtedly a number of ores which can be successfully sulphidized and floated, the method does not present a universal solution of the problems involved. Probably methods will be found for neutralizing the "sulphidicides" just as they were slowly developed for neutralizing "cyanicides" during the growth of cyanidation.

The flotation-oils situation is no longer so acute, as it has been found that there is a great variety of oils which will yield acceptable flotation results, although the best ones are very hard to obtain. A number of scareheads have appeared announcing the value of one or another nostrum for such work, but few of them have resulted in anything. Such has been the fate of shale oil and the products from destructive distillation of gilsonite and similar hydrocarbons.

Greater interest has centered around the various proposals which have been tested in attempting to escape the terms of the patents of the Minerals Separation Co. A number of the larger copper concentrating mills and one or two of the zinc mills began using more than 1 per cent of oil on the weight of the ore, 1 per cent having been said to be the approximate point below which a new effect was produced and for which the Minerals Separation Co. had been able to obtain patent. By the use of as high as 3 per cent of oil in commercial frothing-flotation work it seemed to be very definitely proved that there was no "critical proportion" of oil. This argument formed the basis of the defense in the new lawsuit brought by the Minerals Separation Co. against the Butte & Superior Co. in the Circuit Court at Butte. Nevertheless, the Minerals Separation Co. won the decision, and it has now been appealed and will shortly be tried in the higher court.

With regard to the patent situation, we have wearied of following its details. The stakes are too high for any of the parties involved to give up the fight, and the plaintiff company has changed front repeatedly in trying to claim the whole field of flotation. We have now lost all hope of a satisfactory end to this litigation, and think it not unlikely that the life of the patents will expire before the litigation ends.

Flotation is now in commercial operation in a number of mills for the concentration of molybdenum ores in Canada and in Colorado. The details of its application apparently have been worked out to a satisfactory state for elemental sulphur, such as is found in low-grade sulphur ores, and for alumina resulting from the calcining and leaching of alunite ores in southern Utah. We do not know to just how many new uses the process will be put, but it seems safe to say that there will doubtless be more new applications as time goes on. Taken as a whole, we do not believe that the total tonnage of material treated by flotation processes will increase beyond the tonnage anticipated in 1918. There is a natural limit to everything, and advocates of flotation can well point with pride to the fact that the process is now being used on a greater tonnage of material than is any other metallurgical process outside of the concentration and smelting of iron ores.

Iron and Steel in 1917

THE iron and steel industry underwent startling changes during the year just closed, but in that it was true to character. The year opened with a continuance of the runaway market that had characterized the greater part of 1916, and when through Germany's declaration of ruthless destruction of merchant shipping on February 1 it became apparent that war was practically inevitable the market began to advance still more rapidly. The actual declaration of war on April 6 was followed by further advances, but the character of the market changed. It had long been realized that whenever the European war should end there would be a complete readjustment in iron and steel prices, while with the entrance of the United States into the war it was recognized that an advancing iron and steel market could not continue for an indefinite time. Buying for far-forward deliveries soon ceased, therefore, but that only left the prompt-delivery market freer to advance, and by the end of June a price-level had been reached that cast altogether in the shadow all previous market attainments. The prices at which sales were then being made were approximately double the average prices at which material was being shipped. It became obvious that buyers would be unable to pay these prices on the entire tonnage required. Some were making specialties that enabled them to pay almost any price. Others had relatively low-priced material being delivered to them, and paid the fancy prices only on such small tonnages that their average cost was not greatly increased.

On July 12 President Wilson made his famous appeal to miners and manufacturers that they should "forego unusual profits" and that there should be "one price for all," the Government, its Allies, and the general trade. The iron and steel trade did not seem to adopt the idea with much readiness. Apparently it was not gifted with its usual foresight, but there is reason to suppose that it foresaw the inevitable but could recognize no particular necessity for the existing trade being disturbed. The trade was running under such steam that it had a number of months still to go. Meanwhile no one would suffer particularly, and the Government intended to lay heavy war taxes upon

profits of the entire year 1917. In due time, namely on September 21, the iron and steel trade yielded gracefully to the President's requirements and then made it almost a religion to carry out the price agreement in both letter and spirit. There have been a few recalcitrants, but only a very few indeed. By agreement with the manufacturers, the War Industries Board announced on September 24, October 11 and November 5 certain prices for iron and steel products, while the price-setting for various other commodities was left to the American Iron and Steel Institute, with the understanding that all prices should be in harmony, considering costs, with the basis prices originally set.

The industry has found itself under obligation to furnish a great deal more iron and steel, for the best prosecution of the war, than was originally expected. The early estimates made, say from February 1 to July 1, all referred to material that would be required directly as war munitions for the Government and its Allies. These estimates ran, generally speaking, from 20 to 40 per cent of the output. Afterwards an altogether new viewpoint had to be developed. As President Wilson insisted in his appeal of July 12, although he did not mention any particular commodity, no clean distinction could be drawn between material required directly for war and material merely contributing more or less indirectly towards winning the war.

This fact became clear as to iron and steel. As the country from month to month reached a fuller realization of the industrial forces it would have to mobilize for prosecuting the war to the fullest extent, it was found that the few iron and steel-consuming industries that could not contribute were losing in activity of their own accord, while the great majority of the consuming industries could directly or indirectly aid in prosecuting war. Thus the capacity of the railroads was found to be strained, and more rolling stock, particularly locomotives, is obviously required. Maximum petroleum production is essential, requiring the fullest supply of oil-country tubular goods. The automobile factories, while consuming much less steel for making pleasure cars, are required to make many more trucks, in which heavier steel is used, as, for instance, light plates instead of blue annealed sheets. The one industry that seemed marked for decreased iron and steel consumption, without any compensating increase, the so-called building industry, has largely disappeared without leaving a gap, and yet it has had some special activity. The lettings of fabricated steel in November were heavier than in any of the eleven months preceding, and the lettings were almost entirely in connection with the war.

This complete change in the character of iron and steel activities occurred through the overriding of obstacles that had been considered difficult if not insurmountable. The iron and steel-consuming industries had been regarded as so specialized that only a limited portion of them could be employed for war activities. The iron and steel finishing departments were regarded as so specialized that they could convert only a limited proportion of the crude steel into forms suitable for war purposes. In both cases the specialization had to yield. Factories had to be converted to make war products instead of peace products, and the steel-finishing industry had to go through its own changes. The tradition was that the steel industry had to put such a percentage of its output into merchant bars, such a percentage into plates, and so on. The production in 1916 of sheared plates, ¼ in. and heavier, was only a trifle over 1,800,000 gross tons. Additional plate mills were built and the capacity approximately doubled. The slabbing mill output was entirely absorbed and a large tonnage of blooming-mill slabs is being employed. What has helped materially is that so large a tonnage of steel is required for shells, this steel being chiefly the product of the blooming mill, which thus becomes a general service mill. The supply of sheet bars has been somewhat limited, but the war requires the entire output of the tin mills only, and but a part of the sheet-mill output, and thus the end of 1917 found the tin mills operating full and the sheet mills operating at 50 to 60 per cent of capacity, with everyone moderately well satisfied.

At all times the iron and steel industry has been able to furnish all the iron and steel that could profitably be employed in the work of waging war. The changes required of the consuming industries have been occupying the time. It is a remarkable thing that when the steel industry has been so highly specialized it has been possible to respond so fully to the completely new alignment of demand. That it has been able to do so has been due to the fact that the consuming industries were likewise specialized, and had to undergo their changes.

The iron and steel industry is in position to furnish much more material than hitherto, if it is provided with adequate transportation facilities. It produced 39,400,000 tons of pig iron in 1916, operating its available furnaces practically at capacity, but at the close of 1917 it had capacity equal to 42,000,000 or 43,000,000 tons of pig iron, and had produced only about 38,750,000 tons in the year. There was, and is, a lack of sufficient transportation for Connellsville coke. In steel ingots the 1916 output was 41,400,000 tons and the 1917 output about 42,500,000 tons, but the capacity is nearly if not quite 50,000,000 tons. There have been shortages of pig iron, coal and scrap, due to insufficient transportation.

Taking only 45,000,000 tons as the ingot capacity of the United States, the Allies now have, with Canada, Japan, Italy, France and England, a total steel ingot capacity, actually operative, of close to 65,000,000 tons. The Central Powers started with about 19,000,000 tons in Germany and 4,000,000 tons in Austria, while Belgium's 2,500,000 tons capacity was captured and about 3,500,000 tons of the French capacity, making a total of about 29,000,000 tons, all of which cannot be operated. Steel will win the war, and the first American soldier to give his life on the western line was in the Minette iron-ore district, with the great French and German steel-producing districts before him.

The Western Metallurgical Field

Burro Mountain Concentrator

The Burro Mountain branch of the Phelps-Dodge Corporation has been operating a 1500-ton concentrator at Tyrone, N. M., since April, 1916. The ore, which is recovered from underground workings, consists of disseminated sulphides of copper and iron in a monzonite porphyry, and contains about 2 per cent copper. At present the tailings run approximately 0.5 per cent copper, of which half is copper as oxide. Experiments are now in progress to determine whether additional flotation machines will not reduce the tailing loss.

Water for milling is derived from the mine pumpage, which amounts to about 750 gallons a minute. Tank outflows are returned to circuit by properly placed pumps, and in times of water scarcity some of the water in the tailings ponds is pumped back by centrifugals.

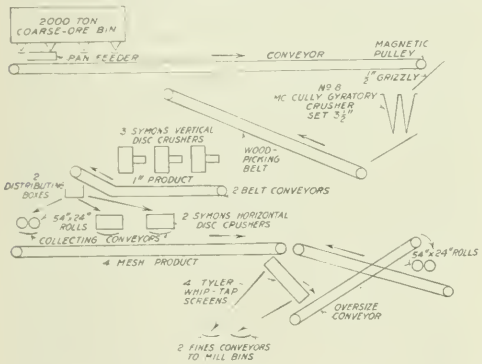

DIAGRAM OF CRUSHER SECTION, BURRO MOUNTAIN MILL

The mill is entirely electric driven, individual motor-drives being used for the most part. About 750 hp. is furnished from the main power plant near the mine, where Diesel oil engines are installed.

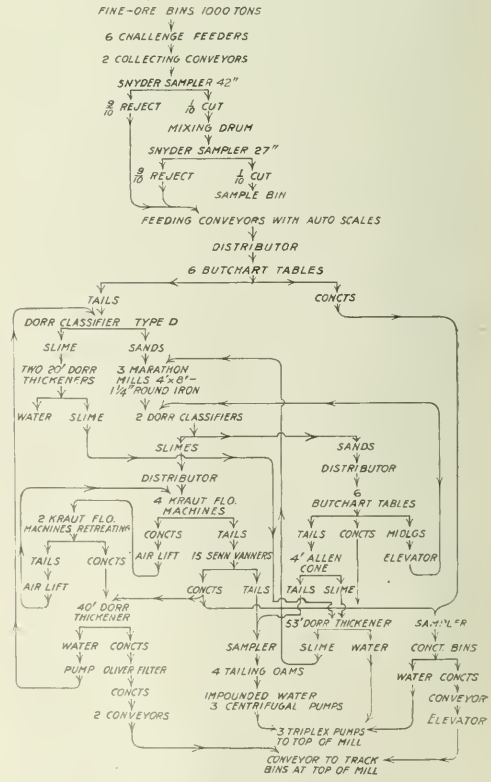
Through the kindness of Mr. J. T. HALL, mill superintendent, we are enabled to present the accompanying flow-sheet. It will be noticed that the crushing division reduces the ore to 4-mesh (Tyler Standard), which is fed directly to a battery of Butchart tables without sizing or classification. Indeed the only sizing done throughout the mill consists of a rough classification in the de-watering drags, where the overflow is called "slimes," and the de-watered material is called "sands." The tailings from the flotation machines run over a battery of Senn vanners, which catch the coarse, and considerable of the very fine, sulphides which did not float. The table and vanner concentrates are settled in rectangular wooden tanks at the bottom of the mill, which tanks are emptied through plug-openings in the bottom, discharging their contents to a belt conveyor which leads to a track at the top of the coarse-ore bins. A spur to the bins is now under construction, and later the concentrates will be delivered directly by belt conveyor to a box-car loader. This material is shipped to the Copper Queen Smelter at Douglas, Ariz., for treatment, about one-fifth of the entire output being a flotation concentrate.

The mill itself is situated on a steep side hill, and all repair parts are delivered on tracks at the topmost level. An incline railway, used during construction, is still in constant use. The carriage on this incline takes push-cars from level to level, where tracks lead directly into each floor of the mill and the various shops. A large jib crane is installed at the dock on top of the hill to handle heavy parts from the railway cars to the incline.

Evolution of Reverberatory Construction at American Smelting and Refining Co. Plant, Hayden, Ariz.

The American Smelting and Refining Company's smelter at Hayden, Ariz., was blown in May, 1912, for the treatment of the concentrates produced by the neighboring Ray Consolidated concentrator and such other custom ores as might present themselves. Originally a two-reverberatory plant, the receipts of smelting material were almost continually in excess of the capacity, until at present the company is installing the fourth reverberatory, 24 ft. by 114 ft. in dimension, oil-fired, and with the usual waste-heat boilers (1500 hp.) and other auxiliaries.

The construction of these furnaces has undergone an interesting evolution. Originally built almost as copies of the successful old Garfield long reverberatory, with a multitude of small buckstays ranged on sides and ends, the firing ends of the first two furnaces were rebuilt to allow side charging through mangers, accord-



FLOW SHEET OF ONE UNIT OF CONCENTRATOR, BURRO MOUNTAIN MILL

ing to the ideas of James Heggie, general superintendent of the El Paso plant of the A. S. & R. Co. This involved piercing the side walls with broad, arched openings, requiring a buckstay-spacing of about nine feet—the thrust of the roof arch being carried by a heavy horizontal girder.

This construction proved to be satisfactory in all respects, and the third reverberatory was accordingly ironed in a similar manner throughout its length, replacing the multitude of small I-beam buckstays by the largest H-beams, in combination with horizontal girders behind the skew-backs to carry the roof thrust. At the same time the arch was carried full width to the skimming end of the furnace, avoiding excessive scour on the bricks at this region.

The objection to this ironing is that it is hardly flexible enough. That is to say, in case of a failure of a portion of the arch between expansion joints, it is almost impossible to regulate the movement of the new section without large and undue distortions in the old roof. This has been corrected by the superintendent, Mr. R. B. GREEN, in the reverberatory now being built by placing a pair of buckstays opposite each expansion joint in the roof and subdividing the horizontal girder so that each section of the roof can be handled as a unit. With such construction a roof-failure can be replaced in a few hours and the furnace again smelting in the time formerly required to cool off the whole furnace.

Although the present reverberatories are oil-fired, the management has decided to replace this fuel with pulverized coal, owing to the increasing price and scarcity of oil. Construction of a 300-ton pulverizing plant has therefore been commenced.

The converter department has seen a corresponding increase in capacity. Originally containing two 10 ft. by 26 ft. Pierce-Smith shells, a 12-ft. Great Falls converter was soon installed to act as a standby. Construction of a large 13 ft. by 30 ft. Pierce-Smith is now under way to care for the matte produced by the added furnace capacity. The brick converter flue, 18 ft. 1 in. by 19 ft. 6 in., in cross-section (hopper-bottomed), will be extended south to a point of higher ground, where a new concrete stack 16 ft. diameter by 250 ft. high, will be built. This will replace the present temporary stack, a square steel skeleton lined with corrugated iron.

When these additions are completed, which will be about July 1, 1918, the Hayden smelter will smelt approximately 2000 tons of charge daily and ship a monthly production of 10,000,000 pounds of blister copper.

De Spirlet Kilns at Argentine, Kans.

The National Zinc Company has been operating zinc blende roasters of the De Spirlet type for about two years, and at the present time has a battery of ten of these kilns in operation. As has been noted in METALLURGICAL & CHEMICAL ENGINEERING, Sept. 1, 1917, page 220, these roasters consist of a succession of round superposed, flat arches, which are alternately fixed or rotating. Rabbling is effected by fire-clay blocks projecting from the roof of the individual hearths. Thus, the top arch forms the roof of the top hearth, and is stationary. The next arch rotates and forms the floor of the top hearth and the roof of the next-to-top hearth; the next is stationary, and so on.

The hearths themselves, 12 ft. 10 in. in diameter, are built within a ring of suitable steel shapes. This ring is placed on a floor and a centering of sand swept up using the familiar pivot and sweep of the loam mold. The bricks, 5 in. thick, are all special, with a key extending around the edges. It has been found that extreme care in matching these bricks for a minimum clearance at the joints will prolong the furnace campaign from four months to a life of one year. Four brick masons complete an arch in three days.

An annular trough of bent angles is riveted to the periphery of these flat arches, which is filled with roasted ore and acts as a seal. Into the channel filled with granular material projects the downstanding leg of another bent angle riveted to the bottom of the corresponding channel just above. This sand seal effectually closes the joint between fixed and moving hearth. The fixed arches are hung from brackets at four columns.

These same brackets each carry a flanged wheel upon which the moving arches rotate. The track consists of the side of a bent railroad rail, to the base of which are bolted segments of a gear, meshing into a motor-driven pinion at one column. The individual arches are assembled into a furnace by traveling crane.

The hearths themselves are quite shallow, hardly 12 in., top to top; while the rabbles clear the bed only 1¼ in. The top hearth acts mostly as a dust chamber, the SO_2 gases being drawn off into collecting flues at the periphery. The ore is automatically charged near the center of the stationary roof and soon is worked through a hole at the center of the rotating bed. The rabbles of the second hearth work the ore toward the periphery, dropping to the bed below, thence to the center, and finally into two hoppers at the edge of the bottom hearth.

The base of this hearth forms the roof of a similar muffle which is heated by a coal flame, the products of combustion being drawn downward through ribbed iron flues to a chimney opening. Air for the roasting of the ore is preheated by being circulated around the cast-iron chimney flues and thence through a muffle just below the combustion chamber. The hot air is then introduced into the drop hole of the lowest ore hearth, and travels in a direction opposite to that of the ore. The SO_2 content of the gases is remarkably uniform, standing at 7 per cent ± 0.5 per cent for hours together. Dusting is extremely low, being only about 4 per cent when working on flotation concentrates. A treater is being installed to precipitate all of this finest dust, in order to clarify the acid made from the smoke. The recovered flue dust is converted into zinc sulphate.

One man tends the three furnaces, his only duties being carefully to loosen accretions from the fireclay rabbles from time to time. Coal consumption is 1 ton ± per furnace. Each furnace treats about 7800 lb. of green ore plus about 1800 lb. spiles, this being average capacity for a full campaign.

The engineers of the National Zinc Company have changed many features of the original De Spirlet design, and feel that real progress has thus been made. They are still experimenting on the furnaces to determine the characteristics best fitted for each individual ore at their disposal.

The Webb Export-Trade Bill.

AN important measure in Congressional legislation looking toward the establishment of American export trade is known as the Webb bill. It has passed both House and Senate, and it is expected that a Conference Committee will reach an agreement on minor differences when Congress reconvenes Jan. 3. The measure is so vital to American trade that we publish it herewith, with the Senate amendments numbered and italicized. The portions stricken by the Senate amendments are enclosed in brackets.

AN ACT

To promote export trade, and for other purposes:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

That the words "export trade" wherever used in this Act mean solely trade or commerce in goods, wares, or merchandise exported, or in the course of being exported from the United States or any Territory thereof to any foreign nation; but the words "export trade" shall not be deemed to include the production, manufacture, or selling for consumption (1) *or for resale,* within the United States or any Territory thereof (2), of such goods, wares, or merchandise, or any act in the course of such production (3) [or] manufacture (4), *or selling for consumption or resale.*

That the words "trade within the United States" wherever used in this Act mean trade or commerce among the several States or in any Territory of the United States, or in the District of Columbia, or between any such Territory and another, or between any such Territory or Territories and any State or States or the District of Columbia, or between the District of Columbia and any State or States.

That the word "association" wherever used in this Act means any corporation or combination, by contract or otherwise, of two or more persons, partnerships, or corporations.

Sec. 2. That nothing contained in the Act entitled "An Act to protect trade and commerce against unlawful restraints and monopolies," approved July second, eighteen hundred and ninety, shall be construed as declaring to be illegal an association entered into for the sole purpose of engaging in export trade and actually engaged solely in such export trade, or an agreement made or act done in the course of export trade by such association, provided such association, agreement, or act is not in restraint of trade within the United States, and is not in restraint of the export trade of any domestic competitor of such association.

And provided further, That such association does not, either in the United States or elsewhere, enter into any agreement, understanding, or conspiracy, or do any act which artificially or (5) [intentionally and unduly] *the natural effect of which enhances* (6) *or depresses* prices within the United States of commodities of the class exported by such association.

Sec. 3. That nothing contained in section seven of the Act entitled "An Act to supplement existing laws against unlawful restraints and monopolies, and for other purposes," approved October fifteenth, nineteen hundred and fourteen, shall be construed to forbid the acquisition or ownership by any corporation of the whole or any part of the stock or other capital of any corporation organized solely for the purpose of engaging in export trade, and actually engaged solely in such export trade, unless the effect of such acquisition or ownership may be to restrain trade or substantially lessen competition within the United States.

Sec. 4. That the prohibition against "unfair methods of competition" and the remedies provided for enforcing said prohibition contained in the Act entitled "An Act to create a Federal Trade Commission, to define its powers and duties, and for other purposes," approved September twenty-sixth, nineteen hundred and fourteen, shall be construed as extending to unfair methods of competition used in export trade against competitors engaged in export trade, even though the acts constituting such unfair methods are done without the territorial jurisdiction of the United States.

Sec. 5. That every association now engaged solely in export trade, within sixty days after the passage of this Act, and every association entered into hereafter which engages solely in export trade, within thirty days after its creation, shall file with the Federal Trade Commission a verified written statement setting forth the location of its offices or places of business and the name and addresses of all its officers and of all its stockholders or members, and if a corporation, a copy of its certificate or articles of incorporation and by-laws, and if unincorporated, a copy of its articles or contract of association, and on the first day of January of each year thereafter it shall make a like statement of the location of its offices or places of business and the names and addresses of all its officers and of all its stockholders or members and of all amendments to and changes in its articles or certificate of incorporation or in its articles or contract of association. It shall also furnish to the commission such information as the commission may require as to its organization, business, conduct, practices, management, and relation to other associations, corporations, partnerships, and individuals. Any association which shall fail so to do shall not have the benefit of the provisions of section two and section three of this Act, and it shall also forfeit to the United States the sum of $100 for each and every day of the continuance of such failure, which forfeiture shall be payable into the Treasury of the United States, and shall be recoverable in a civil suit in the name of the United States brought in the district where the association has its principal office, or in any district in which it shall do business. It shall be the duty of the various district attorneys, under the direction of the Attorney General of the United States, to prosecute for the recovery of the forfeiture. The costs and expenses of such prosecution shall be paid out of the appropriation for the expenses of the courts of the United States.

Whenever the Federal Trade Commission shall have reason to believe that an association or any agreement made or act done by such association is in restraint of trade within the United States or in restraint of the export trade of any domestic competitor of such association, or that an association either in the United States or elsewhere has entered into any agreement, understanding, or conspiracy, or done any act which artificially or intentionally and unduly (7) [affects] *enhances or depresses* prices within the United States of commodities of the class exported by such associa-

tion, it shall summon such association, its officers, and agents to appear before it, and thereafter conduct an investigation into the alleged violations of law. Upon investigation, if it shall conclude that the law has been violated, it may make to such association recommendations for the readjustment of its (8) [business, in order that it may thereafter maintain its organization and management and conduct its business in accordance with law] *organization, business, conduct, practices, or management in order that they may comply with the law.* If such association fails to comply with the recommendations of the Federal Trade Commission, said commission shall refer its findings and recommendations to the Attorney General of the United States for such action thereon as he may deem proper.

For the purpose of enforcing these provisions the Federal Trade Commission shall have all the powers, so far as applicable, given it in "An Act to create a Federal Trade Commission, to define its powers and duties, and for other purposes."

Passed the House of Representatives June 13, 1917.

Attest: SOUTH TRIMBLE, Clerk.

Passed the Senate with amendments Dec. 12, 1917.

Attest: JAMES M. BAKER, Secretary.

United States Tariff Commission Making Inquiry in Regard to Chemical Industries

The Tariff Commission is undertaking an inquiry into the significant developments that have taken place in the chemical industries since the passage of the tariff act of 1913. Changes which seem likely to alter permanently the conditions of international competition or the course or volume of foreign trade are to be special subjects of study.

All persons having direct knowledge of pertinent facts in regard to any particular industry or product are invited to submit a statement to the Tariff Commission. Among the matters on which the Commission desires as full and complete information as possible are:

1. The manufacture within the United States of articles formerly unavailable or obtained exclusively by importation, for example, phosgene.

2. In the case of industries previously established in the United States, the erection of new plants or increase in capacity of existing plants; for example, the increase in capacity of existing plants for making caustic soda and chlorine and the installation of such plants as textile and paper mills.

3. The future of industries or establishments newly created, or in which productive capacity has been greatly increased to meet a direct war demand. How can these plants be utilized when the war demand disappears? For example, the acetone industry.

4. Any general or significant differences in the prevailing method of manufacture in the United States and abroad, such as the relatively small use of the carburetted water-gas process in England compared to the process in the United States.

5. Differences in the organization of the industry in the United States and abroad.

6. The development or invention in the United States or abroad of new or improved processes which are likely to influence the conditions of international competition; for example, the hydrogenation of fatty oils or the flotation process for concentrating ores.

7. Significant changes in the conditions of international competition caused by the recent law making patents owned by citizens of enemy countries available to American manufacturers; for example, the patents on salvarsan.

8. Industries which have been seriously hampered in their normal operations or in their development by difficulty in securing materials or supplies formerly imported; for example, the lack of potash for fertilizer or glass. If these difficulties have been met by the introduction of substitutes, is it expected that there will be a return to the old materials and methods when foreign supplies again become available, or will the changes be permanent?

9. Developments or changes in other industries which have created a new or greatly increased demand for chemical products; for example, the manufacture of new varieties of glass in the United States.

10. The discovery of new uses of materials, creating a new demand or furnishing a market for materials formerly wasted; for example, the use of aniline as an accelerator in the vulcanization of rubber.

11. Any governmental hindrances in the United States or abroad, either in manufacture or commerce; such as the export duty on nitrate from Chile.

The Commission will publish only general statements or summaries, which will not reveal the operation or plans of individual companies.

Attorney General Interprets Laws Bearing on Importation of Distilled Spirits

In response to a request from the Secretary of the Treasury, the Attorney General has given an interpretation of the recent legislation on importation of distilled spirits. The food control act approved August 10, 1917, states: "Nor shall there be imported into the United States any distilled spirits." The revenue act approved Oct. 3, 1917, provides:

"That no distilled spirits produced after the passage of this act shall be imported into the United States from any foreign country, or from the West Indian Islands recently acquired from Denmark (unless produced from products the growth of such islands, and not then into any state or territory or district of United States in which the manufacture or sale of intoxicating liquor is prohibited), or from Porto Rico or the Philippine Islands. Under such rules, regulations and bonds as the Secretary of the Treasury may prescribe, the provisions of this section shall not apply to distilled spirits imported for other than (1) beverage purposes or (2) use in the manufacture or production of any article used or intended for use as a beverage."

The question is: To what extent, if any, does the latter act repeal the earlier?

In answer to this question the Attorney General has given the following opinion:

1. Distilled spirits produced before the passage of the war-revenue act may not be imported for beverage purposes.

2. Distilled spirits produced before the passage of the

war-revenue act may not be imported for any purpose.

3. Distilled spirits produced after the passage of the war-revenue act may be imported for other than beverage purposes and under such rules, regulations and bonds as the Secretary of the Treasury may prescribe.

4. Distilled spirits produced in the West Indian Islands recently acquired from Denmark, if produced from products the growth of the islands and produced after the passage of the war-revenue act, may be imported for any purpose, but if produced before the passage of the war-revenue act their importation for any purpose is prohibited.

Suggestions for Conservation of Coal

Owing to the difficulty of securing customary supplies of coal it becomes necessary to run existing steam power plant with the greatest possible economy. Owners and managers are urged to investigate their power costs and increase efficiency where possible. The Committee on Coal Conservation of the Chamber of Commerce of the United States makes the following suggestions:

Reconsider the advantage of buying heat and power from a specialized plant. In some localities hydroelectric power may be available.

Find the nearest source of coal that will meet the requirements, as this will relieve the tax on our transportation system.

Give to the power plant and its personnel the recognition and encouragement due to an expert and important department. Seek to increase skill and proficiency in the men who handle the coal.

Put the fuel-using equipment into as perfect condition as possible; eliminate leaks in the boiler setting and see that the firedoors fit well. Install simple means by which the fireroom force may see improved results.

Run boilers at capacity, use water free from scale-forming substances, and reduce loss of heat after it is generated by insulating boiler and pipe surfaces.

One pound of coal per hour has yielded a horsepower per hour. That is the record of present possibility. It cannot by any manner of means be attained by every plant. But the fact that at present the average attainment throughout the country is but one-third or one-fourth of this record is indicative of the possible savings that can be made if the care and attention which the power plant deserves are actually given to it.

A Correction

In our issue for Dec. 1, 1917, page 631, Mr. M. Luckiesh contributed an article on "The Physical Basis of Color Technology." Through an inadvertence he did not receive galley proof for correction, and as a consequence the mathematical equations contained a number of errors. We reproduce the equations herewith in correct form to supersede those appearing on page 636 of the issue mentioned:

$$(1)\quad J = J_0 e^{-kd}$$

$$(2)\quad \text{Log}\frac{J}{J_0} = \log T_\lambda = -k_\lambda d \log e = -\varepsilon_\lambda d$$

$$(3)\quad J = J_0 A_\lambda^{cd} \text{ or } T_\lambda = A_\lambda^{cd} \text{ or } \log T_\lambda = cd \log A_\lambda$$

Similar reference characters appearing in the accompanying text should be corrected accordingly.

Council of National Defense Reorganized

On account of the fact that the food control bill provides that corporations whose officials serve on advisory committees are not allowed to enter into contracts with the Government, the Council of National Defense has completed plans for reorganization. Under the new plan prominent industrial men will sever their connections with their industries and go into Government employ, and separate committees will be appointed by the industries themselves. The following statement was issued Dec. 7 by the Council of National Defense.

"The Council of National Defense was established to bring about the co-ordination of industries and resources for the national security and welfare. Previous to the entrance of this country into the war steps were taken by the Council so to mobilize the industries of the country that they could render effective assistance to the nation in its hour of need. The crisis made imperative the necessity for prompt action. Many industries had not been organized in time of peace so as effectively to aid the country in time of war. For these industries to organize themselves, lacking a clear understanding of what the Government would need from them in the emergency, involved delay. Since instant steps were necessary, the Council of National Defense authorized the formation, under its direction, of co-operative committees of industry to be composed of men representative of their respective lines. No other machinery existed or could have been created at that time for the accomplishment of the vital tasks at hand, which primarily were to carry the country through the transition period from peace to war.

"These committees have given faithful, patriotic and invaluable assistance to their country. Many of the individuals serving on them have done so only at great personal and financial sacrifice. The thanks of the entire country is due to these men who unhesitatingly and unselfishly responded to the Government's appeal for aid.

"Technically, however, this necessary emergency machinery set up by the Council was not in the administrative sense ideal as a means for making permanent the mobilization of industry in a democracy at war. Practically it was effective, but the committees were placed before the public in a position unfair both to themselves and to the Government. The Council and its War Industries Board, after giving this matter serious thought for some weeks, have concluded that it is now possible to arrange for meeting the Government's needs through the appointment of highly qualified individuals as Government employees and expert advisers, and also to meet the needs of industry as well as to assist the Government by representative committees created not by the Government but by the industries themselves.

"It therefore has become feasible to discontinue the embarrassing situation wherein the members of the present committes are apparently called upon to act both as Government agents or advisers and at the same time as representatives of the industries. In dissolving the present co-operative committees of industry, which were appointed by and under the direction of the Council, the action is taken only with the highest praise and thanks for their splendid and indispensable work and at the same time with the hope that representative committees of the industry will be formed by the industries themselves at the earliest possible moment. The establishment of such committees, formed so as to entitle them to speak for their entire industries, will render immediately available valuable sources of information upon which the Government can draw in connection with the countless business and industrial problems attendant upon the conduct of the work necessary for the prosecution of the war.

Bernard M. Baruch will remain as commissioner of the raw materials section, which will be divided as follows:

Explosives, chemicals, etc.—L. L. Summers, L. L. Summers & Co., New York.

Nonferrous metals and cement—Eugene Meyer, Jr., New York.

Steel—J. L. Replogle, American Vanadium Company, New York.

Oil—J. F. Guffey, the Philadelphia Company, Pittsburgh.

Bureau of Standards Urges Use of Waste Pottery Bisque

From a circular letter sent by the Pittsburgh Laboratory to makers of glass pots, and others, we give the following extract:

"In work conducted at the Pittsburgh laboratory it has been found that the waste bisque of whiteware potteries is well adapted for use as 'grog' for pots used in the melting of optical glass so urgently needed at the present time for range-finders, gun sights, periscope lenses, etc. The low content of iron oxide in this material and its homogeneous structure render it superior to the crushed pot shell or calcined clay for this specific purpose. A much smaller and limited amount of porcelain bisque may also be used, but it is very important to keep the different kinds of body sharply separated, since porcelain tableware bisque is distinct from floor tile, electrical and sanitary porcelain. The porcelain can be used only in small quantities as a fluxing constituent, while the typical whiteware body is of a refractory nature. It is evident that glazed pottery waste cannot be used, and that we are speaking here of unglazed material. It is estimated that close to 250 tons of whiteware bisque are available per month at the present time, and at a very reasonable price. Appeals to a number of large pottery manufacturers have been answered with most gratifying promptness, which speaks well for their zeal for the common good.

"The whiteware bisque is well suited also for use in the regular glass-pot mixtures, but preference should be given to pots used in the melting of optical or signal glass. The whiteware bisque most suitable for this purpose should have a softening point corresponding to Orton cone No. 30 or above.

"In being employed for this purpose, the bisque is crushed in a jaw crusher or dry pan, screened, and then passed over a magnetic separator for the elimination of metallic iron.

"The Pittsburgh laboratory is ready to give advice concerning the supply and use of this waste material to any one interested, and is ready to make softening point determinations free of charge. Inquiries should be addressed to the Bureau of Standards, Fortieth and Butler Streets, Pittsburgh, Pa."

Industrial Service Section of the Council of National Defense

The Council of National Defense has issued the following statement:

As the demands of the Government for more supplies of all sorts have increased there have necessarily arisen in the various departments placing war orders a considerable number of problems relative to proper adjustment of labor supply to the war needs.

In order to secure a basis of facts on which to work out policies, the Council of National Defense has authorized the director to undertake the following work:

1. To determine present and probable future demands for labor in war industries.

2. To determine in connection with the priorities committee of the War Industries Board the relative priorities of the labor demand.

3. To arrange for the supplying of the demand through the Department of Labor or such other governmental or civilian agencies as can best meet the demand.

4. To determine the needs for dilution of labor, including the introduction of women into industry and recommend policies to be followed in regard thereto.

This work under the council has been put under the immediate charge of Mr. L. C. Marshall, who is designated chief of the section on industrial service. Mr. Marshall comes to this work from the deanship of the School of Commerce and Administration of the University of Chicago. He has given his time recently to the special consideration of labor matters as affecting certain procurement divisions of the War Department, and thus takes up the new work with broad general information and special detailed knowledge of a number of the more pressing problems.

It is not contemplated that there will be created under the council any agencies for executive action with respect to the problems concerned. The purpose is to have under the council a section to which these various labor problems may be brought for common consideration.

The new section will work in close co-operation with the War Industries Board and its priorities committee and will, like the War Industries Board, bring to the council digested information from all Government departments as to the above subjects. Policies can then be worked out to secure the most efficient utilization of existing agencies and to facilitate the development of such new agencies as may be necessary.

Woman's Committee for Engineer Soldiers

An organization known as the Woman's Committee for Engineer Soldiers has been formed in Washington, D. C., with Mrs. Wm. M. Black, wife of General Black, Chief of Engineers, as president, Mrs. Charles Keller vice-president and chairman, Mrs. W. W. Harts secretary, and Mrs. Ulysses Grant, 3d, treasurer.

The object of the Woman's Committee is to see that no engineer soldier leaves this country without the proper knitted garments and to send garments to those already "over there." The National Committee in Washington is to be headquarters for units all over the country, and by purchasing yarn in large wholesale quantities should be able to get better prices and deliveries.

An earnest appeal is made to every man and woman interested in the engineers of the Regular Army, National Army, the Railroad, Forestry, Camouflage, or Labor regiments, to join this organization or to send contributions of money for wool, or finished knitted garments, to supply these hundred thousand men. Dues for membership, amounting to one dollar per year, may be sent to Mrs. Wm. M. Black, 1730 I Street, N. W., or Mrs. Ulysses Grant, 3d, 2204 R Street, N. W., Washington, D. C.

The Allied Purchasing Commission is now located in the new and temporary structure housing the Council of National Defense at Eighteenth and D Streets, Washington, D. C. Manufacturers who are producing or who believe their plants are in a position to produce supplies needed by the Allied Governments should make known this fact to the Allied Purchasing Commission.

Zinc Furnace Temperatures—II

Temperatures of Regenerative Furnaces

BY EDWARD MACKAY JOHNSON
Superintendent Eagle-Picher Lead Co.

CONTINUING the data on furnace temperatures given in METALLURGICAL AND CHEMICAL ENGINEERING Sept. 15, 1917, page 300, I present the accompanying curves plotted from temperatures taken on the furnaces in the checker work during periods of reversing, the first reading being taken just before reversing.

Bristol couples were used. In each case they were inserted the same distance into the checker work ports and luted up with clay. Four couples were used at the same time, with leads to one switch common to all. By this means it was possible to take four readings almost simultaneously. The following explanation of the curve numbers holds good for all curves.

If on long valve, E. or W. side:

No. 1. Top outside checker, gas entering laboratory.
No. 2. Top inside checker, air entering laboratory.
No. 3. Bottom outside checker, gas entering checkerwork.
No. 4. Bottom inside checker, air entering checkerwork.
No. 5. Top outside checker, gases of combustion leaving laboratory of furnace.
No. 6. Top inside checker, gases of combustion leaving laboratory of furnace.
No. 7. Bottom outside checker, gases of combustion leaving checkerwork of furnace.
No. 8. Bottom inside checker, gases of combustion leaving checkerwork of furnace.

Example A: Chart G, furnace No. 4, long valve, east side: Curve No. 1 represents the gas entering the top of the outside checker, and during a period of 20 minutes shows a drop of 65 deg. C. Now upon reversing, No. 5 curve represents this particular spot and shows an increase of 75 deg. C. due to the effect of the hot gases of combustion leaving the furnace.

Example B: Referring to the same chart, consider curve No. 2. This curve represents the air entering the top inside checker and during a period of 20 minutes shows a drop of 105 deg. C. Now upon reversing,

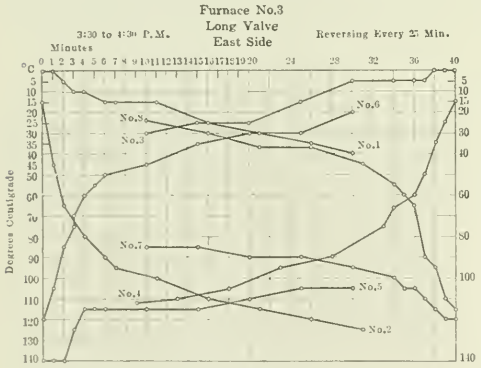


CHART A

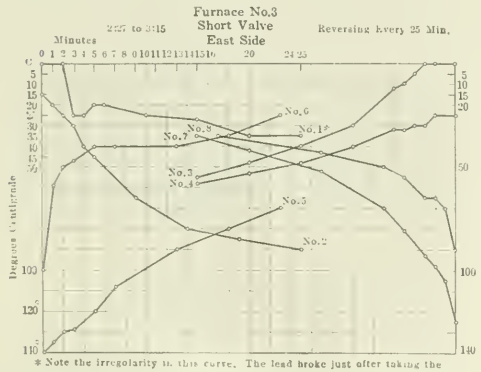

* Note the irregularity in this curve. The lead broke just after taking the reading for this curve.

CHART C

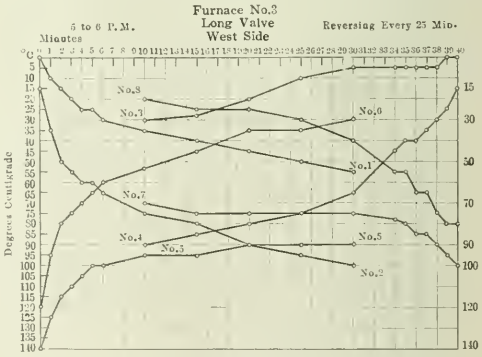

CHART B

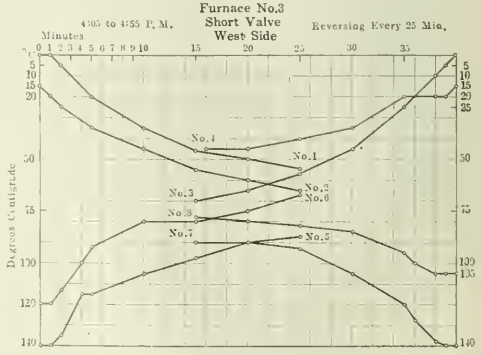

CHART D

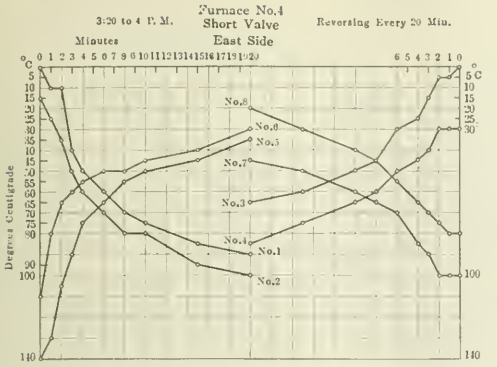

CHART E

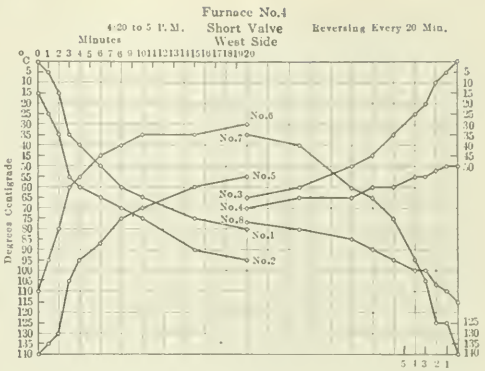

CHART F

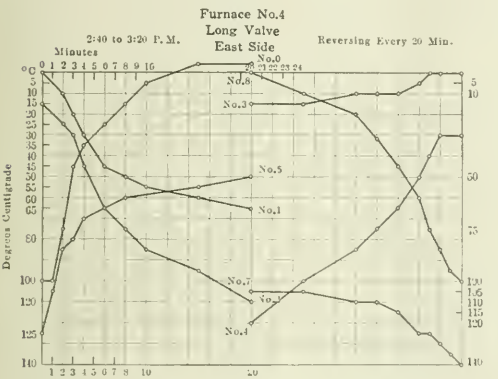

CHART G

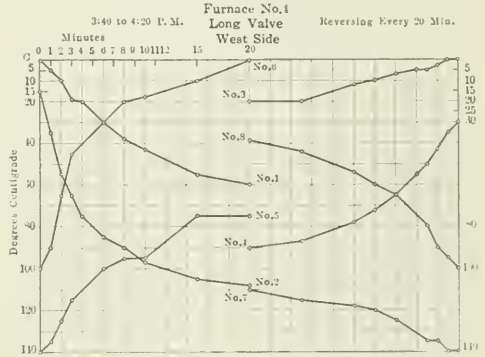

CHART H

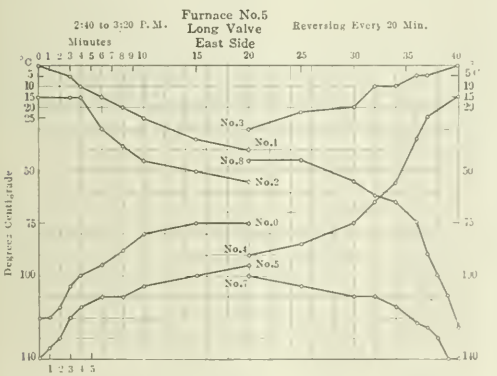

CHART I

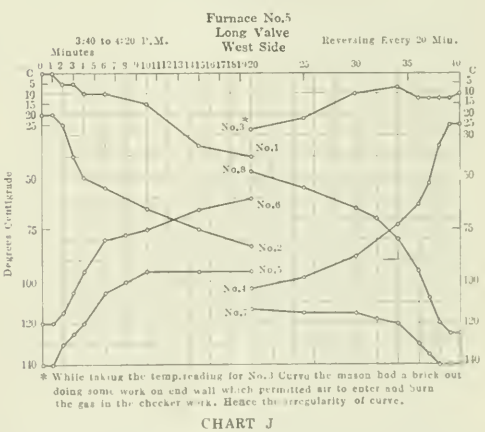

* While taking the temp. reading for No. 1 Curve the mason had a brick out doing some work on end wall which permitted air to enter and burn the gas in the checker work. Hence the irregularity of curve.

CHART J

No. 6 curve represents this particular spot and shows an increase of 105 deg. C. due to the effect of the hot gases of combustion leaving the furnace.

In the same way comparisons may be drawn between curves 3 and 7, and 4 and 8.

Various other comparisons may be made from the curves: As between the long and short valve or between east side and west side, also between inside and outside checkers, from all of which conclusions may be drawn relative to the construction of the checker-work walls, or the height of the checker, or the periods of reversing.

Temperature of Gases Entering Stack

Temperatures taken in the four channels between the valve boxes and the furnace showing a comparison of results during a period of reversals of the gas or air entering on the east side and leaving on the west side, and vice versa, are given in the accompanying tables.

In taking the readings four Bristol pyrometers in-

California yields commercially a greater number and variety of mineral products than any other State and probably more than any other equal area of the earth. Previous to 1916 the total annual value of her output was surpassed by but four other States, they being coal and iron producers east of the Mississippi.

Recent Development of the Côte and Pierron Electric Zinc-Smelting Process

INTERESTING and hitherto unpublished details regarding the most recent step in the evolution of the Côte and Pierron process have just been published by G. Flusin in the *Bulletin Technique de la Suisse Romande* of Nov. 17, 1917 (vol. 43, No. 23, p. 233).

A plant is actually in course of construction at Maurienne, near Epierre; it will be put into operation at the close of this year and its equipment will comprise four furnaces of 500 hp. each. The working capacity of each furnace will amount to four metric tons of zinc ore per 24 hours.

The essential features of the present modification of the C. and P. process are as follows:

1. Treatment of raw ores, without previous roasting (ordinary blendes, fluorspar-containing blendes, mixed ores containing blende and galena).

2. Use of lime and carbon as the only raw materials for the preparation of the fusion bath.

3. Use of a "compound" furnace formed by the cooperation of two adjacent furnaces, viz., one being an "arc-resistance" furnace and the other an "indirect-resistance" furnace, combined in such a manner as to constitute practically only one continuously operated unit. Smelting of the charges is effected roughly to some extent, in the first furnace with liberation of zinc in the form of vapor. The second furnace, which acts as a refiner, receives the crude metal in form of droplets and zinc dust and, without allowing it to cool down, and with an additional small supply of calories, separates it from all the entrained impurities by subjecting it to a second process of distillation, followed by condensation in the fluid condition.

As will be seen, the process consists of effecting fusion of zinc ore in an electric furnace in order to liberate the crude metal therefrom and of refining this metal at once, likewise in an electric furnace, as fast as it is produced while its temperature is still near that of volatilization.

It will be observed that the inventors have given up the method of smelting zinc sulphide ores with iron as desulphurizer and that they have reverted to the smelting of the raw ores in the presence of lime and carbon. On the other hand, they have been successful in avoiding the deleterious effect of CO and other gases and in doing away with intermediate formation of zinc dust.

The ores best suited for this process may have a range of composition as follows: Zn, 30-40 per cent; Pb, 5-15 per cent (incl. Ag.); Fe (as oxide or sulphide), 8-12 per cent; S, 20-30 per cent; CaO, SiO_2 or BaO, 10-15 per cent; Fl, 3-5 per cent; foreign metals, 2-3 per cent; As, 2-3 per cent (tolerated).

The Epierre type of furnace (500 hp.) is capable of smelting 4000-4500 kg. of ore per 24 hours, which corresponds to a current consumption of 2000-2200 kw.-hr. per metric ton of an ore analyzing 35 per cent zinc as the average. Only 1.5 per cent zinc remains in the slag. The metal as it comes from the condenser titrates at once 99.93 per cent zinc. The total losses amount to 8-9 per cent (sometimes only 6-7 per cent). The electrode consumption amounts to 12 kg. per metric ton of ore. The 500 hp. above referred to is distributed as follows: 350-375 absorbed by reactions in the fusion bath, and 150-125 in the condenser.

A Furnace for Testing Refractory Materials Under Load at High Temperatures

By Robert J. Montgomery

Contributed by the Laboratories of the H. Koppers Company and the Pittsburgh By-Product Coke Company

THE furnace described in this paper has been used for two years with complete satisfaction, and it was thought that the design might be of interest to laboratories testing refractory materials.

The accompanying sketch Fig. 1 gives the design in detail. The furnace chamber is circular and may be built of wedge brick, leaving vent holes at various points to allow the inspection of the test pieces. The chamber is heated by two burners using gas and compressed air. These are placed at the level *C* and on a tangent to the chamber. This type of burner gives a whirling action to the flame and a very even heat distribution. The gases escape through the 4-inch circular flue *D* in the center of the bottom between the test brick, which leads to the stack. In order to make sure that the furnace is full of gas and to help in the regulation of the mixture of air and gas, small vent or inspection holes are left open near the top, one above each burner, at the level *E*.

The method of setting the test brick is best shown in Section *AAAAAA*. The brick are set on end on a refractory block *FF*. On the brick are placed the cups *GG*. Then the refractory rods *HH*, which extend through the top of the furnace. This cup and rod arrangement was found to be necessary when tests were made under very severe conditions, such as a 100-pound per square inch load at 1500 deg. C., and it will be found that if the refractories of which the furnace is built are of the same quality as the material tested the furnace will work satisfactorily. The cup takes the highest temperature of the furnace and will not last through many tests, but protects the rod, which will last very well. The cross-sectional area of the rod should be about one and one-half times that of the test piece to stand the strain of severe conditions. The design might be changed somewhat when special refractories are available.

Returning to Section *BB*. On the refractory rod is placed an iron cap *I*, containing a steel knife edge, which engages the grooved plate *J* on the beam *K*. This beam is pivoted at *L* and is balanced by the counter weight *M*. The height of the beam is adjusted by the spindle *N* and hand-wheel *O*. The beam is kept true by the vertical guides *P*. These guides are drilled every inch for a pin support for the beam when the furnace is not in use. The beam acts as a lever in the proportions of one to four, the load being placed on the hook at the

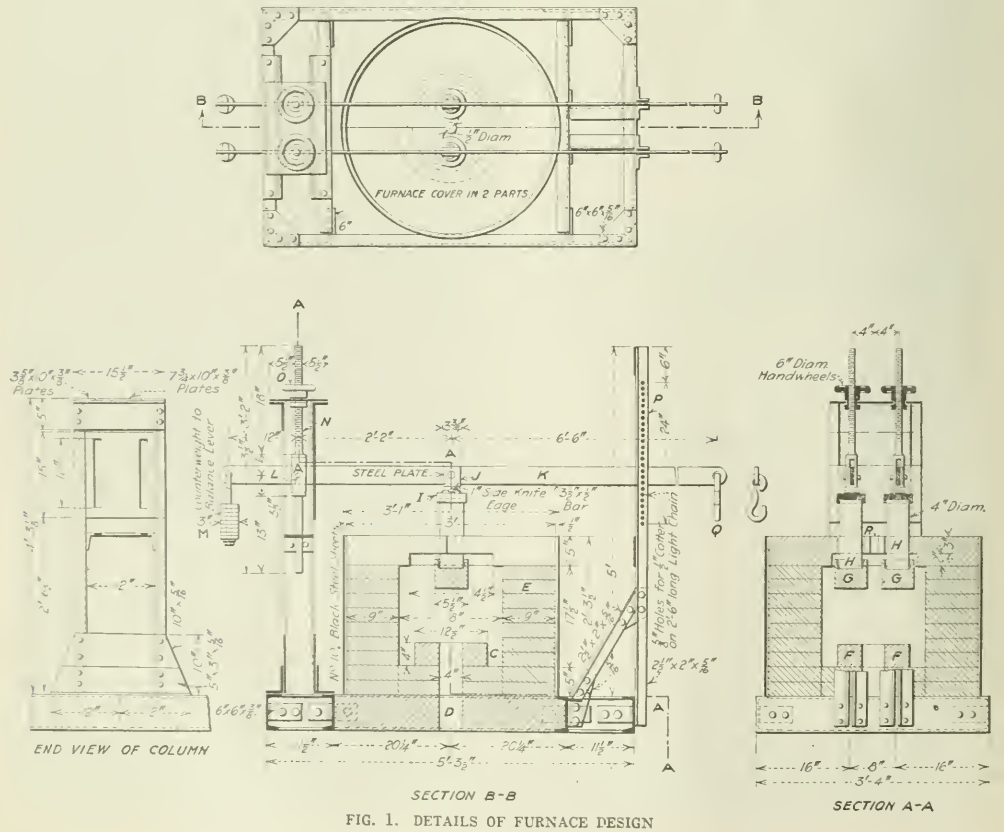

FIG. 1. DETAILS OF FURNACE DESIGN

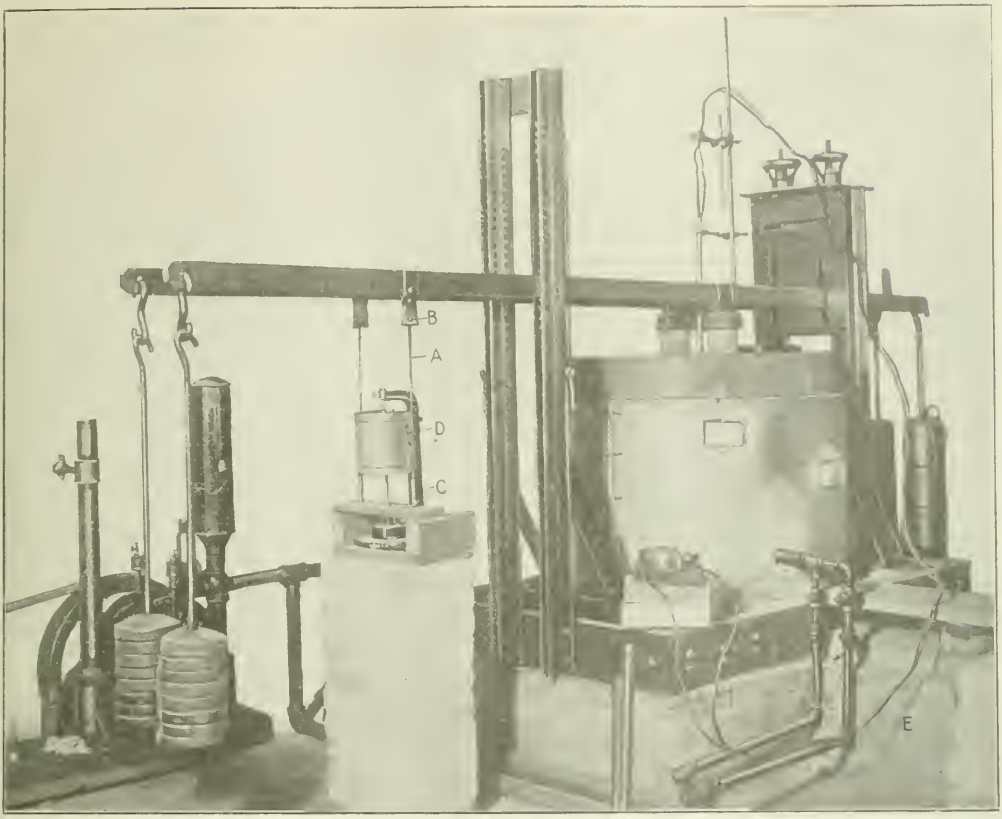

FIG. 2. FURNACE FOR TESTING REFRACTORY MATERIAL

end of the beam. A beam $\frac{3}{4}$ in. by $3\frac{1}{2}$ in. will take a load of 25 to 35 lb. per square inch on a standard sized fire brick without undue deflection and one $\frac{3}{4}$ in. by $3\frac{1}{2}$ in. will take a load of 75 to 100 lb. per square inch.

The beam is leveled at the beginning of the test, and it is not necessary to readjust after starting. The distance between the pivot and the knife edge is great enough not to cause any noticeable eccentric loading. With as high as 15 per cent shrinkage on the test brick the bar is not very far below the original level. By not adjusting the beam a drum recorder may be used to make a complete record of the test. A pyrometer with a three-foot element is inserted through the hole *R* in the cover and extends to the center of the combustion chamber. The cold junction of the couple is protected by an asbestos guard and a correction is made in the readings by adding one-half of the cold junction temperature to the galvanometer reading. The photograph Fig. 2 shows the furnace, with a blower for the air supply in the background. The vent or inspection holes may be seen in the sides of the furnace. The recording device is shown, which gives a movement of three times that of the test brick. The brass rod *A* is pivoted at *B* so as not to bind in the brass guides *C*. A pen *D* is mounted on the rod *A* and it engages the drum recorder. A horizontal flue *E* runs under the furnace to the stack.

Fig. 3 shows sketches of the special shapes required.

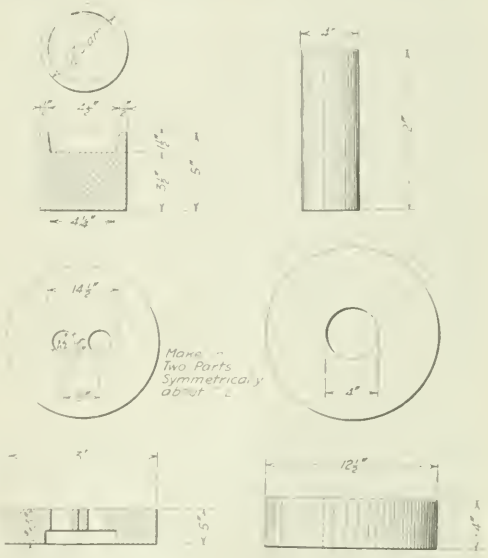

FIG. 3. SPECIAL SHAPES REQUIRED FOR FURNACE

The cover *A* is split through the center to allow the easy adjustment and placing of the test pieces and pyrometer. The ring *B* corresponds to *F* in Fig. 1. As this ring cracks quite easily in operation it could be replaced by two highly refractory brick or special refractory block as the base for the test piece.

The main points in this design are:

1. Two bricks may be tested at the same time, resulting in considerable economy.

2. A down-draft feature which increases the uniformity of the temperature throughout the combustion chamber.

3. The circular combustion chamber and tangential burners give better heat distribution than burners placed at right angles to the furnace.

4. A proper proportioning of the refractory cup and rods allowing maximum temperature and load to be used for the refractory tested.

5. A simple means of applying the load and of obtaining a continuous record of the test.

Disadvantages of Chrome Brick in Copper Reverberatory Furnaces

IN a paper to be presented at the meeting of the American Institute of Mining Engineers in New York, in February, 1918, Mr. FRANCIS R. PYNE offers the following notes on the disadvantages of chrome brick in reverberatory furnaces handling material too valuable to allow of much absorption by the brick.

Several years ago one of the large Eastern copper refineries decided to utilize basic material in place of siliceous material in the walls of their reverberatory furnaces for the treatment of very foul blister copper, as the latter rapidly corroded the siliceous linings.

Magnesite brick were first used, but while the corrosive action of the foul material was greatly reduced, and the amount of slag formed was very much less, the magnesite proved to be unsatisfactory in certain parts of the furnace, because of its tendency to crack and spall badly when subjected to the alternate heating and cooling that takes place in a reverberatory refining furnace. It was therefore decided to substitute chrome brick for magnesite brick in the parts of the furnace affected. The results, as far as the reverberatory furnace was concerned, were very satisfactory. The corrosion due to the action of the foul blister was small and the amount of slag formed was no greater than when using magnesite, and the tendency to crack and spall shown by the magnesite was eliminated. Gradually the use of chrome brick was extended to all furnaces, those treating blister copper as well as those melting cathodes, and the results were so satisfactory that the siliceous roofs were replaced by roofs of chrome brick except in certain places where experience showed a more satisfactory performance on the part of the silica brick.

It was immediately recognized, both for the magnesite and chrome brick, that the metal absorption was very heavy, but it was felt that the longer life of the furnaces and the decreased cost of slag treatment and metal losses would more than offset this disadvantage.

When repairs had to be made to the furnaces, the resulting cobbing was sent to the blast furnaces for the recovery of the copper, silver and gold contents. It was, of course, realized that chrome was a neutral material and could not be fluxed, but it was thought that, at the blast furnace temperature, the cobbing would be melted, releasing the locked-up values and causing the chromium oxide to pass out mixed with the blast-furnace slag.

For a time this method appeared to be satisfactory, but as more of the cobbing was made and treated in the blast furnaces, trouble developed. The capacity of the settlers began to be seriously reduced and slag losses increased, due to improper settling. On investigation, it was found that there had formed in the settler, between the matte and the regular slag, a layer of thick, mushy slag which was causing the trouble.

This mushy slag could not be fluxed, could not be tapped out with the matte, and would not of itself overflow through the slag spout. The only way it could be removed from the settler, without shutting down and digging it out, was to insert a pipe into the layer and by the use of compressed air cause it to mix and overflow with the regular slag. While this procedure cleaned out the settler, it also resulted in metal losses that could not be tolerated. Samples of this mushy slag showed it to contain as high as 25 per cent chromium oxide, indicating that the cause was in the chrome cobbing added to the charge. Upon discontinuing the treatment of the cobbing, the settler trouble disappeared. The natural result of this was to accumulate a considerable stock of the chrome cobbing, and experiments were undertaken to devise a satisfactory process for the removal of the values that would leave a residue that could be sent to the dump.

The cobbing was crushed fine, thereby releasing the larger metallic particles, and treated in a reverberatory furnace with roasted pyritic ore and silica. This treatment gave a fairly fluid slag in which the chromium was apparently soluble. A considerable amount of the metal values was thus recovered, but the slag was still too rich in copper to throw away, and when sent to the blast furnaces induced a return of the former settler troubles.

Fine crushing and fusion with a very low-grade matte was expected to remove the values and leave a slag sufficiently low in copper to be discarded. The results were unsatisfactory, for though the matte absorbed much of the values, yet the slag was thick and pasty and contained considerable copper.

It was felt that crushing followed by mechanical concentration might result in separating the metal from the brick. Accordingly, the material was crushed and screened to remove the coarse metallics and was then treated on a Wilfley table. There was sizing, but little concentration.

Flotation was also tried without success, as the concentrate was too rich in chromium and there were too many values in the residue.

The most satisfactory solution yet found for the disposal of this material is to grind it, thereby freeing the larger metallic particles, and utilize the fine material in the manufacture of refractory brick, thus using the cobbing over and over again. There is, of course, some slagging action and a certain amount of chromium goes to the blast furnace where the mushy slag is formed, but in small amounts it is easily taken care of, and eventually the accumulated stock will be "worn out" and sent to the dump. There are also possibilities of treating this material by converting it into ferrochrome or by making chromate salts.

Our Resources

Address Delivered at the Tenth Annual Meeting of the American Institute of Chemical Engineers, St. Louis

BY G. W. THOMPSON
President, American Institute of Chemical Engineers

WHEN we speak of resources we usually have in mind material things, such as financial, mineral and agricultural resources. It would appear, however, that this is a rather limited construction of the meaning of the word "resources," for with all of these material resources there is the presupposition that one has the ability to use them. Wealth owned by an idiot may not be to him a resource, but rather a liability. A mining deposit that no one knows how to work is hardly worth calling a resource. Wonderfully fertile fields in the centre of Africa are not resources, to the extent that they are removed from the intelligent use of civilized men. In our own country it is true that wealth, mineral deposits, and fertile fields are resources, but they are such because there are resourceful men in our country who can use them. If the present war teaches us anything, it is this: In these days wars cannot be won because a nation has great material resources only, but rather because a nation has resourceful men.

Let us consider this carefully and see whether what I have said is true and what, if it is true, it implies. Mexico is a country that is wonderfully rich in possibilities. Unfortunately for Mexico, whatever the cause may be, the Mexicans have not, themselves, so far developed their possible resources to their country's full advantage. In so far as these resources have been well developed, it has been because resourceful men have gone to Mexico and endeavored to turn mineral and agricultural resources to profitable ends.

The mechanical ability of the citizens of the United States has been recognized all over the world. Give him a mechanical problem, and it is not long before that problem is solved. His agricultural machinery, his machines for the manufacturing of food products, his machines for the stamping and molding of metal, his machines for the utilization of electrical energy, and hundreds of other kinds of machines are evidences of the great mechanical resourcefulness of our citizens.

It should be borne in mind, however, that the mechanical engineer's peculiar field lies in the taking of materials and turning them into machines. The materials must be furnished to him. On whom then does this furnishing of materials to the mechanical engineer mostly depend? I think it will be admitted that the furnishing of materials depends mostly upon the chemist. All of our smelting operations are highly developed chemical manufacturing processes. After metals have been won they must be combined together and with non-metallic elements, in order that they shall be serviceable to the mechanical engineer. Agriculture is a chemical process, and agricultural products must be treated or prepared chemically before they can be used to the best advantage. It may be that it is not as generally recognized as it should be that all smelting and agricultural operations are chemical operations; nevertheless we as chemists perceive this truth as a reality.

We see, therefore, that machines cannot be made unless the materials needed for them have been provided, and we see also that the production of raw and semi-raw materials depends, to a great extent, upon the resourcefulness of the chemist. Whatever the material resources of a country may be, these resources cannot be made fully effective unless efficient chemical processes for their utilization have been worked out.

I must say a few words here, lest I be misunderstood and be thought to be claiming too much for the chemist. In the development of a process for the production of the chemical elements or compounds, the chemist is essential. To make these products on a commercial scale, the mechanical engineer or his equivalent is also necessary. By the equivalent of the mechanical engineer we mean the person who knows how to apply material forces to machines and appliances so as to obtain effective results, and one also who knows how to construct these machines. The person who knows chemistry and chemical processes adequately and who also has a broad knowledge of the field of mechanical engineering, constitutes that modern product of which each of the members of our Institute is a representative—the chemical engineer.

Analysis and synthesis, to a certain extent, parallel each other. In analysis we seek to know the ultimate composition of substances; that is, the elements they contain. Having this information, we then seek to know how these elements are chemically combined; i. e., the constitution of the chemical compounds present. There are, therefore, two limits which confront the analyst. In making an ultimate analysis he cannot go beyond the elements themselves. He cannot decompose them into other constituents. The time may come when he will be able to do this, but the prospects are that that time is a long way off. The other limit lies in his determination of the constitution of chemical compounds. This is not a fixed limit, and the information we are obtaining every day is shoving this limit further back and widening the chemist's horizon. So, too, with the synthesist. He has the same fixed limit as the analyst. He cannot combine substances to produce elements, and he has a similarly continually widening limit as to the compounds that he can synthesize. He is adding continually to the superstructure which rests upon analysis.

Methods of Developing Material Resources

The materials which a country needs may be obtained from its material resources in four ways, in all of which ways the chemist is preëminently the active factor.

First: By the production of commercially pure elements from minerals, such production being by methods which may with propriety be called analytical. In this way lead, silver, copper, etc., are obtained.

Second: By the production of such chemical compounds as are found in mineral deposits or in plant

and animal bodies. These compounds are isolated by methods that are also essentially analytical. In this way common salt, cane sugar, glycerine, etc., are obtained.

Third: By the production by synthetical methods of such chemical compounds as are referred to in Class Two. In this way indigo has been produced.

Fourth: By the production by synthetical methods of compounds not produced by nature, i. e., not found in mineral deposits or in plant and animal bodies. In this way innumerable inorganic compounds such as the salts of the heavy metals, and many inorganic compounds such as the so-called coal-tar dyes, have been obtained.

It is not to be assumed that these are the only ways in which the chemist is the active factor in the production of useful materials, but the four classes of materials given serve as a basis for the systematic study of our resources.

We will attempt now to review, in as general and condensed a way as possible, some of the resources of our country and the relation of the chemist to them, what he has done, what apparently he will be unable to do, and what we may hope for him in the future.

Considering the chemical elements which are included in Class One, it is quite evident that we have a reasonably ample supply of the minerals which contain the following elements: aluminium, arsenic, barium, boron, calcium, copper, carbon, iron, lead, magnesium, phosphorus, silver, sodium, titanium, and zinc. It is true that under pre-war conditions some of these elements, or the minerals containing them, were imported, but they were all produced in this country and the amount imported was insignificant as compared with home production. Elements such as arsenic, barium, calcium, magnesium, phosphorus, and sodium were mostly used in chemical compounds. Arsenic was produced mostly as a by-product of smelting operations, in the form of white arsenic. Barium was produced mostly as mineral barium sulphate or barite. Calcium and magnesium were produced to some extent as metals but were mostly in the form of chemical compounds. Phosphorus was produced to some extent as an element but was mostly used in fertilizers as acid phosphates. Sodium was produced in large quantities in the metallic form but was mostly used in chemical compounds such as caustic soda and sodium carbonate. The modern chemist gave us methods of producing aluminium, magnesium, phosphorus and sodium. The modern chemist has developed practically all of the metallurgical processes on which the production of copper, gold, iron, lead, silver, and zinc rests. He gave us the electrolytic refining of copper, the cyanide process for the recovery of gold, the structural knowledge of steel, the Bessemer and open-hearth processes for making steel, processes for the electrolytic refining of lead, and processes for the electrolytic production of zinc. All of these contributions of the chemist have greatly increased the output of these elements and rendered them more available for useful purposes. It is obvious, of course, that we have an ample supply of such elements as chlorine, hydrogen, nitrogen, oxygen, and silicon, all of which the chemist uses in the production of chemical compounds.

For some years before the war the production of bromine was a profitable industry, in spite of the unfair competitive conditions under which it labored.

In the case of carbon, we have an ample supply, although in its allotropic forms, graphite and diamond, we have not all of the supplies that could be desired. The chemist, however, has given us an artificial graphite which, to a great extent, has supplied our needs for this material, and he has also given us abrasive compounds that approach the diamond in hardness. With regard to all of these elements, the chemist is continually contributing to their more economical production and use.

We must not neglect to mention sulphur, which, when converted to sulphuric acid, is the basis, practically, of all chemical industries. Although large quantities of pyrite have heretofore been imported, the importation of sulphur itself has fallen to a negligible amount, due to the production of sulphur by the methods developed by Frasch. It would appear also that the recovery of sulphur compounds from smelter gases would, under normal conditions, more than supply our needs, taken together with our other sources of production. At the present time the supply of sulphuric acid may be considered as inadequate, but this is due only to extraordinary demands created by the war, and it would seem probable that even those demands could be met satisfactorily at an early date.

There are some elements of which we have no appreciable supply. One conspicuous example is iodine. Practically the entire world's production of iodine comes from Chile, where iodine is obtained as a by-product of the nitrate industry. If the need were great enough, however, iodine could be obtained by the old-fashioned method—from seaweed.

Antimony has been very little produced in this country, probably due to economic reasons, although scattered deposits have been found and worked. If the need were great enough, undoubtedly antimony could be produced. We are fortunate, however, in having a large quantity of antimony in the form of antimonial lead which is obtained as a by-product of the lead smelting industry, antimonial lead being suitable for most purposes where antimony and lead together are used. If the need came, there would be little trouble for the chemist to separate the antimony from the lead.

It is rather curious that there has not been a great quantity of manganese ore produced in this country. Just why this production has lagged is rather difficult to say with certainty. Manganese deposits exist, and even if they are not of the particular grade desired, say in the steel industry, their purification by chemical means is not difficult. The cheapness of manganese ores and recovered manganese obtained from abroad before the war was probably principally responsible for our undeveloped production here. It is true that a large quantity of manganese is obtained as a by-product from zinc ores in New Jersey, but that supplies only a small part of our needs. Should the importation of manganese ores and products be rendered more difficult, it would seem that the only way that the required amount of manganese could be obtained would be by the development of our own deposits and probably the calling in of the chemical engineer to develop methods of separation and purification.

We have no platinum deposits in our own country, but there are great quantities of platinum in the country in the form of jewelry, etc., that should be available for the war needs of our country.

We have no great deposits of nickel and cobalt and it would appear that we must depend, for some time at least, upon the Canadian supplies, it being very fortunate for us that we are on such friendly relations with our Canadian brothers.

Since the war began our lack of a supply of potassium salts has been manifest, not merely to us but to Germany, the country from which our supplies mostly came. It is evident that this shortage must be met, and it can only be met by the help of the resourceful chemist. It is not due to the absence of potassium from our mineral deposits that we have not been able to supply ourselves, but it is due to the fact that before the war started, the production of potassium in this country was not developed as a commercial proposition. There are large quantities of potassium in our feldspar, in our alkaline lakes, and in various materials used for the production of Portland cement and beet sugar. There are great quantities of potassium in seaweeds. The production of potassium compounds must be developed. Our country must be supplied, and it is up to the chemists to supply it. Considerable quantities have already been supplied and larger supplies may be expected.

We have no tin deposits of great value in this country, although tin is a widely distributed element, especially in the southeastern states. There seems to be no probability that the chemist will be able to do very much in the near future in the way of giving us a supply of tin ore. He has, however, been of invaluable assistance in the development of processes for the recovery of tin from tin scrap, and it would seem as if at some time in the future, when the stress is sufficiently great, methods will be developed for the collection of much larger quantities of used tin articles and their treatment by detinning processes whereby this semi-precious metal will be recovered.

There are many other elements, more or less rare, to which I could refer. What we have endeavored to show so far is that with regard to most of the elements the chemist has been an important factor in their production, and that the chemist promises, with some few exceptions, to be a still more important factor in the future.

Importance of Synthetic Products

We now come to Class Two, which are those chemical compounds found in mineral deposits or in plant or animal bodies. It would be convenient for us, however, to consider Class Three in connection with Class Two. In Class Three we have those chemical compounds referred to in Class Two, which have been produced by synthetical methods. With very few exceptions, the inorganic compounds included in Class Two, where the need has arisen, have been synthesized and appear in Class Three. It is true that certain minerals have not been synthesized in the physical form corresponding to the mineral; thus asbestos is mined as a mineral product and there has been no demand for the production of anything similar to asbestos by a synthetic method, as the supply which mostly comes from Canada has been reasonably ample.

So too with cryolite used in the electrolytic manufacture of aluminium. It is imported almost entirely.

It is when we come to organic compounds that the significance of our classification becomes more striking, and the chemist must admit that, while great progress has been made in the knowledge of the constitution of organic compounds found in nature, the development of their commercial production synthetically has not made as great a progress as could be desired. It is true that some of the natural dye-stuffs, such as indigo, have been produced synthetically, but there still remains a very large field which is unworked. It seems probable that the lack of progress in this direction has been due to the abundance of our supplies. Our country has had ample quantities of sugar, starch, turpentine, oils, and fats, and hydrocarbons for its needs. It has been easier to produce these things by depending upon "mother nature" than it has been to work out synthetic processes. There need be no criticism of the chemist for this fact, but in the stress of war it is brought home to us how desirable it would have been if certain arts had been developed from our synthetic knowledge that would be available in our present struggle. There are certain things which we do not produce in appreciable quantities, such as shellac, rubber, and the fossil gums. Rubber has been produced synthetically, but, for some mysterious reason, when the methods were announced, the supply of rubber from natural sources became so great that the production of synthetic rubber was rendered unattractive commercially if for no other reason.

During the war the demand for glycerine has become very great. Some day a commercially profitable method for synthesizing glycerine will be developed. Perhaps we have learned our lesson so well that that day is nearer at hand than we dare hope. Let it not be supposed, however, that the chemist has not been active in these two important fields. While he has not developed, commercially, processes that actually synthesize many organic compounds of commercial value and produced by nature, the chemist has transformed many chemical substances into compounds of greater commercial value. The chemist has converted various oils into edible products. He has also, by hydrogenation, changed liquid oils to solid fats, bringing about a much closer parity in price between oils and fats of various origins. He has developed methods for more cheaply producing alcohol and acetic acid. He has produced sugars from starch. He has produced synthetic resins which, to some extent at least, have replaced shellac and the fossil gums. He has produced rubber substitutes which have at least the merit of having kept down to some extent the price of genuine rubber goods. He has developed methods for the recovery of rubber from waste products. He has converted mineral oil into satisfactory substitutes for turpentine. He has continually added to the yield of these natural and other products, by the study of the natural processes by which they are elaborated.

We must not neglect to mention the most important compounds found in nature, of which we have no natural supply. I refer to the nitrates. We have no nitrate deposits, but in that respect we are not less favored than most other nations. The nitrate supplies of the world, for a great many years, have come from one part of the west coast of South America. Germany was one of the first countries to realize its deficiency in this respect, and Germany bent its best efforts toward producing nitrates synthetically. At first her supply of synthetic nitrates was developed in Norway where great water-power resources existed. Later, to make herself

more self contained, she developed other processes, so that to-day she is practically independent of South America and Norway. Without discussing the merits of any particular process for producing nitrates, it is apparent to us that it will not be long before our country has adequate supplies. Partly, it may be by processes originally developed in this country, involving the direct combination of nitrogen with oxygen, and partly, by other processes involving first the production of ammonia and then its oxidation. It seems probable that next to sulphuric acid, nitric acid is the most important chemical needed in the development of our industries, and we should look forward to the much delayed time when nitrogen compounds will become more available.

It is in Class Four, however, that the chemist has been so conspicuously effective, for in Class Four we have those compounds which are not found in minerals or in plant or animal bodies, but are essentially artificial compounds. Here we could fill a long list, if we were permitted, of the inorganic compounds alone that the chemist has produced from every one of the elements by combining it with others. If we attempted to list the organic compounds produced, the list would probably be longer than that of the inorganic compounds. So far these purely synthetic compounds have not shown themselves to possess food values, but as decorative materials, as preservatives, and as medicinals their use has been very great. In the dye industry the artificial dyes have largely displaced natural dyes.

Considering the foregoing as a description of the four classes of materials which constitute the material resources of our country, a very proper criticism could be made that this account is very crude and inadequate. It serves, however, the purpose I have had in mind and which I have already outlined as illustrating the relation of the chemist to our resources, and it serves also as a preface to certain other very important considerations which I will now attempt to outline.

Necessity for Protecting New Arts and Industries

During the present war many processes have been developed in this country for the purpose of increasing our supply of needful materials. Many of these processes have been developed into successful commercial form. Arts have been established.

I think every one who has been instrumental in developing these arts, and many others also, have asked themselves what is to become of these arts when the war is over. Are these arts, due to foreign competition, to become extinct and lost as it were, or will they be able to stand on their own feet in face of that competition? The answers to these questions will vary according to the arts. Some have, undoubtedly, become firmly established and will withstand foreign competition. Others, undoubtedly, will tend to become lost arts, and this tendency should be considered as most unfortunate. Now is the time to study this question and prepare to meet it when the war is over; meet it if need be by allowing the arts to perish, or, if it is more desirable to maintain the arts, by appropriate methods of procedure.

Let us consider this by way of illustration. As indicated above, the production of potash in this country is not to-day equal to the demands of our country. It would seem probable that when the war is over, if Germany follows its old practice of unfair competition, the potash industry will have to cease operations. Potash can be produced in Germany and sold here probably cheaper than we can make it in the near future. A great deal of money has been expended in the development of the art of producing potash in this country. Shall we allow that art to become extinct?

Our government has prepared for the expenditure of a large sum of money for the fixation of nitrogen and the production of nitrates. It can hardly be expected that when the war is over and the demand for nitrates falls off, that immediately the processes and arts which have been developed will be able to withstand the competition of Chile. Nitrates can be produced in Chile at a figure which will probably be lower than what they will be produced for in our government plants when the war is over, unless the war lasts for a long time.

Artificial rubber has never been manufactured in this country. Chemical processes involving its production synthetically may be known. The war has created a great demand for rubber. Should the war last long enough, it might be profitable to develop the production of synthetic rubber, and after the war the art would find difficulty in living.

This prospect of any art perishing in our country is not a pleasing one to me, because it involves a loss of resourcefulness which to me is of more importance than a loss of resources.

The examples I have referred to are by no means the best examples that could be selected. Each of you can probably suggest a better example. They serve our purposes, however, and indicate our needs. They present to us a problem which deserves very careful consideration. Many solutions of the problem can be offered. Undoubtedly, in the case of nitrates, the production can be continued even at a loss after the war is over, provided sufficient pressure is brought to bear upon our legislators.

In the case of potash the problem is somewhat different. Such production is to-day in private hands, and it would appear unreasonable to expect private capital to continue for any length of time to operate a losing or unprofitable business. Undoubtedly, after the war is over more potash will be produced at a profit in this country than there was produced before the war, but the amount will be insignificant. I hold no brief for any potash manufacturer and do not know, directly or indirectly, anyone engaged in such manufacture. Therefore what I have to say is entirely disinterested. We have to-day government-controlled industries. This government control of industries is a war measure. I would hesitate to advocate any control of industries, in general, in times of peace, but wherever there is a case like the potash industry, which is very important to the life and progress of our nation, it seems to me that we have a special case involving special forms of treatment and consideration. It is not very desirable now that any branch of the potash industry be made a government-controlled industry, but when peace comes it seems desirable that some, at least, of the potash industries be put under government control, so that the arts so far developed will be maintained and further development provided for. I believe that the potash industry should be controlled and subsidized, the ex-

pense of the subsidy perhaps being met by a very small tax upon imported potash.

In the case of artificial rubber, it would seem that the rubber manufacturers could afford to organize an institute which would be profitable to all the manufacturers and be for the purpose of developing methods for the production of artificial rubber and allied products. It seems that here government assistance should not be necessary as in the case of potash. The rubber manufacturers should, if practicable, establish an art which could be controlled by patents, each of the rubber manufacturers deriving proportional benefit.

What we have suggested with reference to the nitrate, potash, and rubber industries, should be considered only as types. Perhaps there are other products in regard to which a method of treatment could be developed similar to that suggested in these three cases.

What I have endeavored to indicate in this paper is this: It is not sufficient for us to consider simply what our resources may be, but we should also consider how our resourcefulness can be developed. Undoubtedly much can be done by the education and employment of more chemists and the better education of each chemist. Much can be done by the broader and more intelligent education of chemical engineers, but there still remains the problem of maintaining such arts as have been developed during the war, and the further development of the new and old arts which are now successfully practiced. In some cases I firmly believe that the maintenance of these new arts and the development of other newer arts cannot be accomplished unless there is a broader conception of the advantages of community action based upon community interests.

Brooklyn, N. Y.

The Use of Culm and Other Waste Materials from Coal-Washing Plants for Other Purposes

BY JOHN B. C. KERSHAW

ONE unlooked-for result of the increased cost of labor and transport in all manufacturing countries is that the "dumps" of waste-fuel in colliery districts are growing in size, and that the proportion of fuel left in the mines as "unmarketable" and not worth bringing to the surface, is far greater than is desirable from the point of view of national economy.

Large consumers of fuel, in towns and cities far distant from the coal-mining areas, have in fact now recognized the absurdity of paying high freight and railway charges upon such incombustible matter as water and ash. Consequently washed and properly graded coals are rapidly growing in favor with these classes of consumer. The coal-washing and cleaning plants at the pits tend, therefore, to multiply in all up-to-date mining centers, and the dumps of culm and other washery refuse are growing in size and in economic value.

So far the attempts to utilize this waste material for steam-raising, or other power purposes, have been confined chiefly to the mining companies themselves, but with the extension of their plants the time is rapidly approaching when they will be unable to burn or gasify even a small proportion of their total output of this low-grade fuel, and its sale to outside consumers will become necessary.

Owing to the high percentage of incombustible matter, it will not pay to transport the material far from the mining centers where it is produced, but within a certain limited radius of five or ten miles, culm and washery refuse, when burnt under steam boilers or gasified in producers, form very valuable cheap fuels for power generation.

Special types of furnace grate and of gas producer are, however, necessary in order to obtain good results with these materials, and pertinent facts and figures are here given, based upon recent practical trials in England, America and Germany.

THE UNITED KINGDOM

The early attempts to utilize low-grade fuels for steam-raising in the United Kingdom were made in furnaces of the "destructor" type, for it was recognized that it would be impossible to obtain a decent evaporative efficiency from fuel, often containing from 25 to 35 per cent of ash, in the ordinary type of boiler furnace.

Goodrich, in the *Engineering Magazine* some years ago, pointed out that a Lancashire boiler with a grate area of only 38 sq. ft., could not possibly maintain its proper rate of efficiency with a fuel, the evaporative efficiency of which was at the best only 4 lb. of water per pound of fuel, and he proposed that the grate area should be doubled, and that compressed air should be employed to support the combustion. External brick cells with grate areas of from 50 to 75 sq. ft. were therefore provided, and under these conditions, with forced draft, an evaporation of 10,000 lb. of water per hour, with a Lancashire boiler measuring 30 by 8 ft., became possible. This Dutch-oven type of furnace, however, while quite useful for large sized material like "culm" and the "brasses" from hand-picked coal, was found to be impracticable when fine-grained material and the refuse from coke-washeries had to be burned, and the Bettington type of tubular boiler has now come to the front, as the most suitable for steam-raising purposes, with these classes of finely divided low-grade fuel. This boiler has often been described in the technical press, and some of the latest tests with it are recorded in the *Journal* of the Society of Chemical Industry (1917), p. 114.

Professor Cobb, however, in a paper read in April last before the Midland Section of the British Coke-Oven Manufacturers' Association, has pointed out that the Bettington boiler will require modification in some re-

spects before it can completely burn large-sized grains of coal and coke. The time during which the particles remain in the combustion zone of the boiler with the present design is far too short to allow of their complete combustion. The question of the best materials for the refractory lining of the boiler is also not yet settled, for the high temperature and the molten ash or slag combined have a most destructive action upon it. However, these difficulties will no doubt be overcome in time, and when they are the Bettington boiler will no doubt prove the most efficient type of steam producer, when fired with the finely divided waste materials from coal-cleaning plants and coke-washeries.

The coal-dust that accumulates upon the floors and edges of mines, and proves such an added danger when explosions occur, could also be collected and utilized for steam production if a battery of Bettington boilers were installed at or near the pit-head in all coal-mining districts.

Colliery Dumps Used for Gas Production

As regards the use of waste fuels for producer work in the United Kingdom, Fernald in Technical Paper No. 128 of the Bureau of Mines (published in 1915), gives some figures obtained from the manager of a large English colliery and iron works which had been equipped with a mechanically operated eccentric-grate gas-producer. Several types of producer have been designed for working with fuels high in ash content, and the more successful are provided with some form of revolving eccentric grate for removing the ash automatically, and for preventing blocks due to the formation of large masses of clinker in the lower part of the shaft. In the best form of these producers the degree of eccentricity and the speed of the grate can be varied to suit the amount and the fusibility of the ash formed by the fuel used.

In the particular case referred to above, a water-jacketed revolving-grate producer was installed for the purpose of utilizing the "batts" from the mine dumps of waste fuel, "batts" being the local term for the larger pieces of shale containing a good proportion of coal. It has been found in practice, however, that better results can be obtained by crushing the larger material, and by passing both the large and small through a washing-plant before charging into the producer. In this way the dump at this mine is being gradually reduced in size, 115 tons of the unwashed material yielding 60 tons of nuts (classified as Nos. 1, 2 and 3) and 40 tons of slack. The sample of the original waste-fuel taken from the dump tested as follows: Moisture 6.99 per cent, ash 52.12 per cent, volatile matter 18.37 per cent, fixed carbon 22.52 per cent, and the calorific value of the undried fuel was 5065 B.t.u. After washing, the fuel tested: Moisture 5.85 per cent, ash 24.60 per cent, volatile matter 28.75 per cent, fixed carbon 40.79 per cent, and the calorific value of the undried fuel had increased to 9869 B.t.u. The manager stated that the producers operated well with this washed material, and that their success in dealing with it was due to the water-jacket. The slag contained on an average only 4 per cent of combustible.

Coke Breeze or "Ballast" for Gas Production

In the publication referred to above, Fernald also gives some details of the utilization in England of coke "ballast," which is the name given to the "fines" produced when screening coke. The gases from the producers in this case were employed for firing brick kilns and were non-by-product producers, with stationary grates. The "ballast" used showed the following composition as regards size: 40 per cent passed through a $\frac{1}{2}$-in. sieve, 19 per cent was between $\frac{1}{2}$ in. and $\frac{1}{4}$ in., 14 per cent between $\frac{1}{4}$ in. and $\frac{1}{8}$ in., and 27 per cent was less than $\frac{1}{8}$ in. The analysis of this material gave the following figures: Moisture 10.77 per cent, ash 12.05 per cent, volatile matter 4.92 per cent, fixed carbon 72.26 per cent, calorific value, in B.t.u., 11,160.

The fuel was therefore not a low-grade fuel in the sense that the ash content was high, but simply on account of its fine state of subdivision. In recent years a considerable demand for this class of fuel has been created by electric power engineers, who use it for mixing with the cheaper varieties of bituminous fuel before burning this under steam boilers. This method of utilizing coke breeze was referred to in the second article of this series, printed in the issue of Metallurgical and Chemical Engineering for Sept. 1, 1917.

AMERICA

One of the most notable installations in America for utilizing the refuse coal from the washing plant attached to a large mine, is that erected by the Lehigh Coal and Navigation Company at Hauto, Pa., and described in *Electrical World* for May, 1914. This coal mining company mines in the anthracite coal area and places on the market the ordinary commercial sizes of anthracite. Although the calorific value of the refuse from the washing plant is from 9000 to 11,000 B.t.u., there is no profitable sale for it on account of the large proportion of dust it contains.

The original capacity of the power plant was 30,000 kw., but it is to be increased to 100,000 kw., and some idea of the amount of refuse to be dealt with can be obtained from the fact that in the production of the size known as "stove-coal" alone the Lehigh Company turns out enough refuse to run the whole of the enlarged plant. The original plant comprised eight Babcock and Wilcox double-ended units. Each boiler is provided with four grates, half of each set being fired from one side and half from the other. The boilers are of the five-drum bent-tube type, equipped with superheaters, and are designed to carry 225 lb. of steam pressure. Exclusive of the superheaters, each boiler has 10,000 sq. ft. of heating surface. Six of the boilers are equipped with hand-fired dumping grates of special design, and the two remaining units are equipped with automatic traveling grates, a development of the Coxe design. In the case of the hand-fired furnaces the grates are 12 ft. deep and 8 ft. wide, making the total grate area 384 sq. ft. per boiler. Four of the boilers are provided with Acme slotted-top grates and two are equipped with pin-hole tops. In each case about 6 per cent of the total grate area is occupied by air-apertures, the holes or slots being about 3/32 in. wide. The apertures are at the bottom of grooves moulded across the grate-tops, at right angles to each other, giving the appearance of a waffle-iron. The grooves are provided in order to prevent the fine coal from choking the apertures and thereby hindering free circulation of air through the furnace. Other features of the furnace are the use of vertically sliding furnace doors, recessed ash-pit doors, and shaker-

handles to prevent obstruction to the firing aisles, double fire-arches, cinder catchers, ventilation of fire-wall to prevent burn-outs, and independent brick-settings which are not affected by expansion of the metal parts. Double superposed fire-arches are provided so that if the lower one burns out, the upper one will come into use. Between the superposed arches is an air-space through which air is allowed to circulate slowly, in order to prevent the firebrick temperature from reaching such a value that the material deteriorates. The space over the grates is practically a reverberatory furnace, which ensures the complete combustion of the fuel. The fire-arch is 9.5 ft. long and covers two-thirds of the grate-area. The combustion-chamber above the brick wall is unusually large, and is so designed as to reduce the velocity of the gases and allow any unburned fuel to drop back into the fire and be consumed. The gases from four furnaces under each boiler pass up through the central combustion-chamber and then divide at the top, going through two passes, striking the flues and superheaters (of which there are two to each boiler) and then following the vertical uptakes at the boiler heads to the roof of the station, where they join a common stack. Whatever unburned fuel or cinder may be carried over into the first pass of the boilers is thrown out by centrifugal force at the bottom of the pass into a cinder-catcher. The steam is employed to drive three turbo-generators, each of 12,500 kw., generating current at 11,000 volts. When running at their full load and maximum efficiency, these units consume 12.3 lb. steam per kw.-hr. with a vacuum of 28 in. The electric energy is transmitted at 110,000 volts to various coal mines and cement mills located in the vicinity of the Hauto supply station. The transmission line, however, has been designed for long-distance work, and possibly in time the cities of New York and Philadelphia may receive current from this waste-fuel electricity supply station.

Another example of an American coal-mine electric power-station which is using waste-fuel for steam-generation is that provided by the plant of the Cadogan Mine in Armstrong County, Pa., a detailed description of which was published in *Coal Age* on Dec. 2, 1916.

The fuel in this case consists of 50 to 75 per cent refuse from the tipple picking-tables, mixed with slack. The boilers are Heinz watertube boilers, rated at 470 hp. at 150 lb. working pressure, and provided with a grate-area of 84 sq. ft. Each boiler is fed by three mechanically-operated underfeed stokers, forced draft being supplied by one blower-fan driven by two direct-coupled steam engines. The ash is removed by steel cars running on rails directly below the discharging holes of the retorts. The generating plant consists of two 375-kw. alternators coupled direct to Corliss valve steam engines running at 150 r.p.m. These engines consume 21.6 lb. per hp.-hr. at full load, 21.3 lb. at three-quarter load, and 21.8 lb. at half load. The energy developed is used chiefly for cutting, haulage and pumping purposes at the mine, but as transmisison is an important point, it is generated at 2,300 volts, and is converted by motor-generator sets to direct current at 250 volts at the various points where it is required.

The general conclusions that may be drawn from American experience and practice with these low-grade fuels are two: First, it is recognized that some form of artificial draft is requisite for the proper combustion of the smaller sizes of fuel waste, forced fan-draft operated on the "balanced-draft" principle being most favored. Secondly, it has been proved that only in exceptional cases will it pay to grind or pulverize the lump waste fuel in order to burn it in dust form. When the fuel is brought to the surface in this finely divided state this method of burning is, of course, the most efficient, but in nearly all cases the fuel is too poor to pay for the cost of artificial pulverization. The heat produced by burning rich "culm" in the dust form is sufficient to melt all forms of refractory material, but this is an exceptional material, and the greater number of waste fuels contain so large a proportion of ash that when burnt in the dust form the temperature produced is not so high as that attained under ordinary conditions with lump fuel.

GERMANY

Experimental trials were carried out by Butow & Dobblestein in 1910-1911 for the Westphalian Mine Owners' Assoication in connection with the utilization of waste fuels at the mines, and a summary of the results obtained and conclusions reached has been published from time to time in the German mining paper *Glückauf*. Butow and Dobblestein state that low-grade fuels may be classified according to their origin as follows: (1) Coarse-grained material with ash content up to 50 per cent and water up to 20 per cent; (2) fine-grained material with ash content up to 40 per cent and water up to 30 per cent, and (3) small-coke and coke-breeze with ash content up to 30 per cent and water up to 20 per cent. Two methods of utilization for these low-grade fuels are open to the engineer: they may be burned under steam boilers either alone or in conjunction with other materials, or they may be gasified in producers. Fuels of class (1), they assert, can be burned directly without admixture with other material, but the steam-raising efficiency of the boiler is very low, and such fuels can only be employed in large boiler installations. The application of forced draft gives very little advantage in the case of these fuels, and their utilization directly for steam-raising purposes is therefore restricted to special cases. Fuels of classes (2) and (3), when they can be obtained, yield the best results when fired together, this being specially the case with the fine coal from a rich or gas-coal and coke-breeze, which together yield an excellent firing material for steam boilers. In this case the use of forced draft increases the efficiency of the firing. As regards fuels of class (3), Butow and Dobblestein state that these can be fired alone if they contain 10 per cent of volatile matter and if forced draft is available. Coke-breeze containing less than 10 per cent of volatile matter cannot be fired alone, however, and if no fine material from a rich or gas-coal is available for mixture it must be briquetted with the aid of pitch. Should the ash and water contents of the breeze exceed 30 per cent it will not pay, however, to briquette it, and for this material, as for the lowest grades of classes (1) and (2), gasification in producers is the only practicable method of utilization.

In a later report the same two engineers give details of steam-raising tests made in July, 1911, at the mine "Prosper," with low-grade fuels and a traveling-grate stoker. Fuels containing from 9 up to 22 per cent ash and from 2 up to 13 per cent water were used in these tests. The fine coal from the coal-washing plant and the

coke-ashes could in neither case be burned alone, and were in the final tests either burned together or mixed with the other fuels. A Dürr boiler possessing a heating surface of 1640 sq. ft. was employed in the tests. Six tests were made with the following products: (1) Rejected fuel from the washing-plant. (2) No. 1 fuel mixed with coke-ashes in the proportion of 2 to 1. (3) Dust from nut coal mixed with coke-ashes in the proportion of 3 to 1. (4) A mixture of two parts of fine coal-dust with one part of coke-ashes. (5) A mixture of equal parts of fine coal-dust and rejected fuel from the washer. (6) Dust from nut-coal alone. The following results were obtained: Pounds of steam obtained per pound of fuel burned—(1) 5.61, (2) 4.96, (3) 4.16, (5) 4.45, (6) 5.55. Boiler efficiencies—(1) 58.96, (2) 53.18, (3) 42.93, (5) 48.74, (6) 55.95. The cost of 1 ton of steam using rejected fuel from the washing-plant, was only 18 cents, of which total fuel represented 12 cents.

As regards the use of these waste fuels for gasification, Butow and Dobblestein state that the chief difficulty encountered has been the bulk of the slag and ashes which have to be removed, and the tendency of this to fuse together into large masses and to disturb the normal working of the producer. The producers experimented with were (1) the Mond producer and (2) the Erhardt and Schmer producer. Coke-ashes containing 19.4 per cent ash and 20.7 per cent moisture were used. The trial of the Mond producer with this fuel failed, owing to the air-pressure required to burn it being sufficiently great to blow out the water-seal. So far as could be judged from the preliminary results of the test, 35 cu. ft. of gas testing, 112 B.t.u. per cubic foot, would cost 4.7 cents, without any allowance for labor, depreciation or interest charges.

The trials with the Erhardt and Schmer generator were more successful, as this producer possesses a rotary hearth which retained all the fuel in the lower part of the charge in continual motion and thus prevented clinker formation. In this case a mixture of equal proportions of coke-ashes and refuse from the washing and sorting machines at the mine was used, and after the method of burning the generated gas under a Lancashire boiler had been modified very successful results were attained. The following is an estimate of the cost of evaporating 2204 lb. of water with this cheap fuel-refuse:

Labor	9.6 cents
Interest and depreciation	9.6 "
Fuel	6.0 "
Feed water	1.2 "
Power for motor	1.6 "
Total	28.0 cents

For a larger plant this low cost could be still further reduced, as the same labor would suffice for two producers, and 2204 lb. of water could then be evaporated for 24 cents. By use of the gas in a gas-engine, still more favorable results could be attained.

Finally, a report made by Mann and Müstefeld upon the gasification of low-grade fuels, and published in *Glückauf* in 1912, may be referred to. These authors state that the chief characteristic which determines whether a fuel is to be classed as "low-grade" is the fineness of its particles; ash and moisture are of secondary importance. The factors that determine whether any particular low-grade fuel will pay for its gasification are (1) the chemical composition of the gas that can be produced from it, and (2) the cost of obtaining one calorie, or heat-unit, in the gas produced. The chief difficulty in working gas-producers with these low-grade fuels is due to the finely divided state of the particles. This causes great resistance to the air supply inside the producer. Incomplete combustion occurs in consequence and the yield of gas is diminished. Air-channels are also formed in the burning mass of fuel which lead to further disturbances of the normal conditions of work, since these air-channels carry an excessive air-current and result in the formation of CO_2 in place of CO.

The authors give details of trials made with the Mond, Erhardt and Schmer, Maschinen Fabrik Augsburg, and with the Kerpely producers, when using this class of fuel. The steam required to operate the different types of generator varies from 15 to 18 lb. per 100 lb. of fuel in the case of the Kerpely producer, up to 200 lb. in the case of the Mond producer. The Kerpely high-pressure producer is finally described in the form specially designed for gasifying finely divided low-grade fuels. A satisfactory gas composition is obtained from these producers by the use of a great depth of fuel-bed and by a uniform distribution of the air-supply over the whole area of the combustion zone. The ashes and clinkers are continuously removed as the gasification of the fuel proceeds. The following tests show the chemical composition of the gas made in a Kerpely producer during six separate trial-runs.

	1	2	3	4	5	6
CO_2	3.00	5.18	10.0	7.0	2.4	4.1
CO	30.20	26.66	21.9	27.4	32.5	29.5
H	14.85	15.01	22.2	18.3	12.3	14.5
CH_4	.40	1.30	2.0	2.5	.....	1.4

In conclusion, it may be pointed out that the subject of the utilization of these low-grade fuels has a far wider bearing upon the future of American manufacturing industries than is generally recognized. At present from 20 to 35 per cent of the fuel reserves are being left in the mines, because there is no market for the poorer classes of fuel.

Those who imagine that the poorer seams of coal can be worked and brought to the surface when all the richer seams have been exhausted only show their ignorance of mining operations by this belief. It is therefore incumbent upon all who have the future welfare of their country at heart to study the methods of utilizing low-grade fuels, and to do what is possible to create a market for them while the seams are still exposed and their extraction from the mines is a practicable proposition.

Colwyn Bay, North Wales.

New York State Branch of American Ceramic Society.—A meeting was held in Hornell, N. Y., on Nov. 19 and 20 for the organization of a New York State Branch of the American Ceramic Society. The following officers were elected for 1918: President, L. E. Barringer, Schenectady; vice-president, Frederick Carder, Corning; secretary, J. B. Shaw, Alfred. It was decided that a meeting should be held quarterly, the next meeting to be called in May at either Syracuse or Schenectady.

A Volume Regulator for Blast-Furnace Engines*

By L. C. Loewenstein

BLAST-FURNACE operation has attained a high degree of refinement in the proportioning of the various materials composing the charge—the ore, the fuel and the flux. The weight of oxygen—introduced as atmospheric air—per charge has, however, until recently been subject to much uncertainty due primarily to the difficulty of measuring with any degree of accuracy the volume of air delivered. The adjustment of the air supply to the furnace was, therefore, usually made only when the operator found evidence that the furnace was badly overblown or underblown, a process which resulted in a more-or-less variable product and certainly in a reduction in the possible maximum output of the furnace.

With the advent of the centrifugal compressor giving a perfectly steady air blast, the metering of the air supply became more practical and, therefore, more usual. With perfectly definite and uniform charging a definite and uniform weight of air per minute is desirable. Constant-volume governors have been designed on two principles, one by metering the air by means of a venturi meter and the other by using an impact float. The venturi-meter governing has been improved by using a multiple venturi meter in which large pressure drop can be obtained in the throat without a corresponding loss in power. This difference in pressure is used on a mercury pot whose motion up and down is translated to the governing mechanism of the driver of the air compressor. The proper setting of this meter is accomplished by changing the tension of the spring until a scale calibrated in cubic feet of air per minute shows that the desired quantity of air is obtained.

In the impact float method the air is taken through a conical opening in which is suspended a float, this float moving a horizontal beam about a pivot. The horizontal beam actuates the governing mechanism of the driver of the air compressor. On this horizontal beam is a sliding weight which can be set at calibrated marks representing cubic feet of free air per minute. With the weight set in a definite position a certain definite quantity of air is obtained.

In both of these methods, however, the readings on the calibrated scale are only correct when the initial air conditions are standard, that is, are similar in barometer, temperature and humidity to which the scale has been calibrated. Any change in either the temperature of the inlet air or in the atmospheric barometer or in the humidity of the air, changes the weight of the air metered, and, therefore, its oxygen content. As the blast furnace requires an exact weight of oxygen, the above method of holding constant volume is liable, in extreme cases, to have an error of from 15 to 20 per cent.

The Volume Corrector

A volume corrector is herewith presented which when used in connection with the air-metering device will correct for any changes in either temperature, barometer and humidity, so that the air supplied to a blast furnace will, at all times, under any atmospheric conditions, deliver a perfectly definite and predetermined weight of oxygen to the blast furnace. This volume corrector is so designed that it requires only one setting for each correction, that is, one setting for any initial temperature, one setting for any existing barometer and one setting for humidity as usually obtained by the difference of readings on a wet-and dry-bulb thermometer.

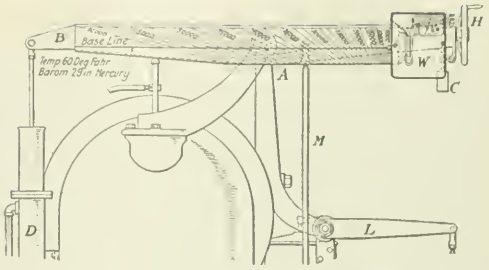

FIG. 1. VOLUME CORRECTOR APPLIED TO IMPACT FLOAT GOVERNOR

It can be applied to the sliding weight and calibrated scale of an impact-float constant-volume governor for correcting this governor when handling air of any temperature, barometer or humidity. An instrument similar in principle and somewhat similar in construction can also be applied to the indicating mercury column of the venturi meter so as to obtain proper volume correction.

The volume corrector applied to the impact-float constant-volume governor is shown in Fig. 1. The scale beam *B*, instead of having vertical calibration lines for standard conditions of air, has sloping constant-volume lines engraved upon it. The volume corrector proper is mounted on the front of the sliding weight *W*.

Fig. 2 shows the arrangement of this instrument. There are three milled heads, *A*, *B* and *C*, provided for

*Abstract of a paper presented at the annual meeting of the American Institute of Mechanical Engineers, December, 1917.

adjusting pointers indicating barometer, temperature and humidity. All that is required of the operator is to set these pointers correctly. After obtaining the actual barometer reading from a standard barometer, and the actual temperature of the incoming air, and observing the existing humidity—which is usually done by noting the temperature difference between a wet- and dry-bulb thermometer, pointer *a* is set at the proper barometric reading, pointer *b* at the proper temperature reading, and pointer *c* moved so as to intersect the curve corresponding to the observed temperature difference between the wet- and dry-bulb thermometers.

The movement of each of these pointers influences the final position of the main pointer *P*. This main pointer moves in a vertical direction with respect to the scale on the beam. After the volume corrector is properly set, the sliding weight to which the volume corrector is permanently attached is moved horizontally along the beam until the main pointer *P* intersects the sloping line on the graduated scale designating the proper volume of standard air required. When so set the sliding weight is in the proper position. This permits corrections to be made for variation in temperature, barometer and humidity so that a constant *weight* of oxygen is supplied no matter what the conditions of the atmospheric air. Having determined that the blast furnace requires a definite volume of standard air (dry air at 60 deg. Fahr. and 29 in. Hg), the governor with corrected setting of the sliding weight will deliver the proper amount of actual air which would contain the same *weight* of oxygen as would be contained in the required quantity of standard air.

Principles of the Corrector

The amount of oxygen in dry air varies directly as the density of the air. The density of air is directly proportional to the barometric pressure and inversely proportional to the absolute temperature. Expressed symbolically, $\gamma \propto \frac{B}{T}$. As the float force is proportional to $\frac{M^2}{\gamma}$, a change in density γ with the governor set to maintain a constant weight M of air per second will cause the governor to change the speed of the compressor until a new weight M_1 is delivered, such that the new value of $\frac{M_1^2}{\gamma_1}$ is the same as the original value of $\frac{M^2}{\gamma}$. Expressed symbolically, for a given setting of the sliding weight $M^2 \propto \gamma$, or $M \propto \sqrt{\gamma} \propto \sqrt{\frac{B}{T}}$. For moist air the barometer no longer represents the pressure of the air itself, for part of the barometric pressure is due to the vapor pressure in the air. This vapor pressure must therefore be subtracted from the observed barometric pressure in order to get the net air pressure to be used in computing the air density and hence the weight of oxygen per cubic foot of air. For saturated air (a relative humidity of 100 per cent) the vapor pressure can be read directly from steam tables for the observed atmospheric temperature. If the air is not quite saturated the relative humidity, or the percentage of the possible maximum of moisture in the air, can be determined in a number of ways; usually, from a dry- and wet-bulb thermometer arrangement. The vapor pressure for a given temperature is proportional to the relative humidity, and this must then be subtracted from the observed barometric pressure in computing the air density.

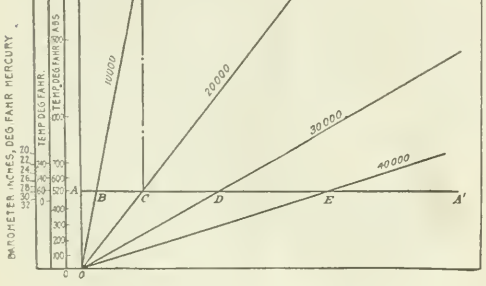

FIG. 3. METHOD OF GRADUATING BEAM

The graduated scale on the beam of the constant-volume governor was designed by taking a horizontal base line such as shown schematically in Fig. 3 as *AA'*, and placing thereon the proper calibration for standard air (dry, 60 deg. Fahr., 29 in. Hg.). The zero on this line gives the position of the sliding weight when the constant-volume governor beam is in equilibrium and no air is flowing. The point *B* (Fig. 3) represents the position of the sliding weight for 10,000 cu. ft. flow; and point *C* its position for 20,000 cu. ft. flow, etc. The distance *AC* is made equal to four times *AB*. Similarly the distance *AD*, where *D* represents the 30,000 cu. ft. point, is made equal to nine times *AB*. With respect to temperature, the graduations on the *AA'* hold good so long as the prevailing atmospheric temperature is 520 deg. Fahr. absolute. When the prevailing temperature is other than 520 deg. Fahr. absolute, the relations of the distances *AB*, *AC*, *AD* to each other remain unchanged; but they must all be multiplied or foreshortened by the same ratio. This is accomplished in the following manner:

Referring to Fig. 3, let the line *OAB'* be perpendicular to the base line *AA'*; and let *OA* represent to some scale 520 deg. Fahr. absolute, and *OB'* represent 2080 deg. Fahr. absolute to the same scale, so that *OB'* = 4 *OA*. Draw *B'C'* parallel to *AA'* and *CC'* parallel to *OB'*. Also prolong the straight line *OB* until it intersects the line *B'C'* in the point *P* (not shown). The triangles *OAB* and *OB'P* being similar, *B'P* : *AB* : : *OB'*:*OA*; or *B'P* = 4 *AB*. But *B'C'* = *AC* = 4 *AB*. Therefore *B'P* = *B'C'*; or *P* coincides with *C'*. In other words, the intersection *C'* of the line *CC'* with *B'C'* is a point on the straight line OB.

Now in actual operation, when the governor is set to deliver 20,000 cu. ft. of standard air per minute for a temperature of 520 deg. Fahr. and should the actual temperature be four times as high, or 2080 deg. Fahr. absolute, the governor will, as explained before, with the same setting of the sliding weight, regulate for only 10,000 cu. ft. of standard air per minute, because the density of the air at 2080 deg. Fahr. absolute is one-

fourth of that at 520 deg. Fahr. absolute. The pointer of the sliding weight must under those conditions then read 10,000 cu. ft. without the sliding weight itself being disturbed in any way. In the volume corrector this would be accomplished by pushing up the final pointer along a uniform temperature scale until it reads 2080 deg. Fahr. absolute, because the pointer traveling upward would then, as proved above, just intersect the 10,000 cu. ft. line *OBC*. It will be noticed that all the sloping lines representing definite volumes of air per minute meet at *C*. This would represent the point of absolute zero if the same temperature scale was carried down on the prolongation of the line *AB*. From the above it can be seen that if the volume corrector be made to carry a temperature scale with the same distances as employed in the engraving of the scale on the beam, and the main pointer *P* of the volume corrector be made to move vertically up and down the proper distance to this scale, the sliding weight can be set for any observed temperature of atmospheric air so as to deliver the proper volume of air containing the same weight of oxygen as is contained in the previously calculated necessary volume of air of standard conditions.

Further consideration will show that as far as the density or the square of the volume is concerned, doubling the absolute temperature is equivalent to halving the barometer. In other words, any barometric change can be expressed by an equivalent temperature change. For instance, if 29 in. Hg is taken as the standard barometer and 60 deg. Fahr. (520 deg. absolute) as the standard temperature, a change to 28 in. barometer, the temperature remaining at 60 deg. Fahr., is equivalent to a change to a temperature $\frac{29 \times 520}{28}$ or 538.6 deg. Fahr. absolute (78.6 deg. Fahr.) with the barometer remaining at 29 in. Hg. The distance on the barometer scale from 29 in. to 28 in. must, therefore, equal the distance from 60 deg. Fahr. to 78.6 deg. Fahr. on the thermometer scale, whereas the correction necessary from 29 in. Hg to 25 in. Hg barometer is equivalent to a change to a temperature of $\frac{29 \times 520}{25}$ or 603.2 deg. Fahr. absolute (143.2 deg. Fahr.) with the barometer remaining at 29 in. Hg. The distance on the barometer scale from 29 in. to 25 in. must therefore equal the distance from 60 deg. Fahr. to 143.2 deg. Fahr.

The barometric scale constructed on the above principle for the volume corrector is evidently a reverse and reciprocal (that is, non-uniform) scale. For constructional reasons, and chiefly to take care of humidity corrections explained later, it is desirable to have this scale uniform without affecting in any way the accuracy of the instrument. This is accomplished in the following manner:

Referring to Fig. 4, which gives a view of the volume corrector shown in Fig. 2, but with some of the front cover plate removed, *A*, *B* and *C* are the pins to which the milled heads *A*, *B* and *C* are attached. The main pointer in Fig. 2 is moved up and down in a vertical slot by means of pin *p* in Fig. 4. When the operator moves milled head *A* so that pointer *a* indicates the barometer reading, gearwheel *D* (Fig. 4) rotates about pin *A* because it is meshed into a rack *E* which remains stationary. Motion is given to pin *p* (which is held in vertical slot) by the slot *S* in gearwheel *D*. This slot is in the form of a cam and so designed that pin *p*, and therefore the main pointer *P*, moves the proper distance vertically. The main pointer will move a less distance vertically when barometer pointer moves from 32 in. to 31 in. than it will when moving from 31 in. to 30 in., and less from 31 in. to 30 in. than it will from 30 in. to 29 in. Therefore, although the barometer scale over which pointer *A* moves has uniform divisions, the actual vertical distance through which the main pointer *P* moves is non-uniform and follows a reciprocal scale.

The setting of temperature is accomplished through milled head *B*, which is attached to a plate movable vertically between gibs *GG* and which carries with it the rack *E*, gearwheel *D*, and pin *p* with main pointer *P*. Moving *B* up and down does not revolve gearwheel *D* at all (that is, does not disturb the barometer setting), but simply moves main pointer *P* over a temperature scale shown in Fig. 2. Pointer *b* is set opposite the proper temperature reading.

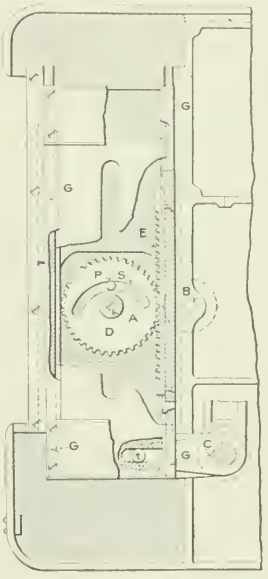

FIG. 4. INTERIOR END OF REGULATOR

The corrections for humidity in the volume corrector are based upon the following considerations: The barometric - pressure reading as usually observed is equal to the sum of the air pressure plus the vapor pressure. If the air is saturated, that is, if it contains all the water vapor it is capable of holding without precipitation at the particular temperature, the value of the vapor pressure at the given temperature can be ascertained experimentally or taken from the steam tables. If the degree of saturation or the relative humidity is, say, only 20 per cent or 50 per cent, then the vapor pressure as determined experimentally must be multiplied by 0.20 or 0.50 as the case may be.

The most usual method of ascertaining the relative humidity of the air is by means of a wet- and dry-bulb thermometer arrangement. In its simplest form it consists of two similar thermometers, the bulb of one of which is covered by a wet piece of sponge. If the air is fully saturated no evaporation into it can take place and the two thermometers record the same temperature. When the air is only partly saturated, the evaporation from the wet bulb lowers the thermometer reading; so that the difference in the readings of the wet and dry thermometers can be taken as a measure of the relative humidity of the air. For any combination of relative humidity and atmospheric temperature the vapor pres-

sure is a definite quantity. This vapor pressure must be subtracted from the observed barometer reading in order to give the net or correct air pressure to be used on the barometer scale above described; since it is the density (and therefore the actual pressure) of the air alone that is of importance, and not the density of the mixture of air and water vapor.

It is important to note that the humidity correction in pounds per square inch or in inches of mercury is independent of the actual barometer reading, and depends only on the atmospheric temperature and on the difference between the wet- and dry-bulb thermometer readings (relative humidity). The humidity correction can therefore be made mechanically if the pointer *P* on the sliding weight is given an additional correction or movement which would be the equivalent amount of a certain subtraction of pressure on the barometric scale equal to the correction for the pressure due to vapor. It is for this reason that it is preferable to make the divisions on the barometric scale uniform, so that, for instance, a half-inch mercury correction would require the same movement no matter at what reading the barometer scale happened to be set. As will be shown later, the volume corrector accomplishes this, therefore no matter where the barometer pointer *a* is set, the humidity correction moves the main pointer *P* on the sliding weight the proper amount. It will also be noticed that the humidity is a function of the atmospheric temperature, that is, when the temperature is high the water vapor in the saturated air is higher than when the temperature is low. In the volume corrector the setting of the temperature pointer *b* on the temperature scale automatically sets the humidity pointer *c* to the correct temperature also.

Referring to Fig. 2, the correction for humidity is made by loosening milled head *C* and swinging pointer *c* until it intersects or indicates the proper amount of difference in reading between the wet- and dry-bulb thermometer. The movement of the long arm carrying pointer *c* about the center of milled head *C* moves pin *t* attached to a plate carrying gearwheel *D*, but does not move rack *E*. Moving gearwheel *D* vertically up or down rotates *D* because *E* is stationary and thereby moves the main pointer *P* similarly, as heretofore described.

Accurate Constant-Volume Governing

The volume corrector therefore is an instrument which can be set by an operator at the existing barometer, temperature and humidity of the atmospheric air, and when so set will permit the setting of the sliding weight on the scale beam in a position so that the constant-volume governor will hold or deliver the correct volume of air which would contain the same weight of oxygen as would be contained in a certain predetermined and desired volume of standard air.

This means that the blast-furnace operator, knowing the chemical compositions of the coke and iron ore and the amounts charged to the furnace in a stated period of time, can determine the exact volume of standard air (dry, 60 deg. fahr., 29 in. Hg) which will contain the proper amount of oxygen necessary for combustion of the coke and reduction of the iron ore on the blast furnace. He need not perform any mathematical calculations as to how much more or how much less air must be supplied when the atmospheric conditions are not those considered standard in order to be sure the blast furnace is receiving at all times its exact and necessary weight of oxygen.

The volume corrector needs resetting every time the operator notices any change in the barometer, temperature or difference between the wet- and dry-bulb thermometer reading in order to be sure of securing the most efficient regulation. The air conditions, however, do not vary rapidly and the practice of inserting in an engine-room log every half hour the steam pressure, r.p.m., vacuum and other information can easily be extended to include readings of the barometer, thermometer and wet- and dry-bulb instrument. Even with the front cover of the volume corrector closed, transparent places are provided which will permit any one checking or observing these settings. The need of a volume corrector is apparent from the fact that it is possible to have a variation of weight of oxygen delivered to a furnace of 5 to 10 per cent ordinarily and in extreme cases as high as 20 per cent as a result of variations in atmospheric-air conditions, especially as between winter and summer. The gains in quality and quantity of output of a blast furnace obtained even by the former methods of constant-volume governing without volume corrections will be still further improved by the use of constant-volume governing with proper volume corrections.

West Lynn, Mass.

Close Watch on German Trade Preparations.—German preparations for trade after the war are being scrutinized carefully by experts in the Bureau of Foreign and Domestic Commerce, and the recent important report on the subject of "German Foreign Trade Organization," by Chauncey D. Snow, which touched on this point, has been in great demand. Since the war eliminated Germany from world trade, the United States has improved its position in foreign markets in spite of the shipping shortage and other abnormal restrictive factors. Department officials point out that the future prosperity of the country will depend in part on Germany's loss of good-will in practically all foreign markets and in part upon American ability to maintain our new prestige. American business must not make the mistake of seeing only one side of this situation and thus underestimating the German capacity for foreign trade or the energy, application, and craft with which German business will address itself to the task of regaining favor in markets in which it once prospered. In order to understand the significance of the information on German trade moves that will from time to time be made public, Secretary Redfield counsels not imitation of but familiarity with the German theories of foreign trade and the artful and formidable organization that, with Government aid at every turn, has been built up in Germany during the last twenty years to dominate the world's markets. It was to meet the demand for such information that the Bureau of Foreign and Domestic Commerce issued the bulletin on "German Foreign Trade Organization." The unprecedented demand for it is taken as an indication that the American manufacturer is making after-war preparations of his own. The Bureau now plans to get out about the first of the year a supplementary bulletin on German trade and preparations for the commercial future.

Bibliography on the Extraction of Potash

From Complex Mineral Silicates, Such as Feldspar, Leucite and Glauconite (Greensand Marl)

By E. C. BUCK

LESS progress has been made in the production of potash from silicate rocks than from other natural resources, such as brines and kelp. Nevertheless, a vast amount of work has been done on the subject and numerous processes have been patented. It is believed that the following bibliography will prove timely. It includes all references to patents and periodical literature relating to the sintering of phosphatic rocks with feldspathic rocks—a process which is held to be of great promise, since the potash is at once obtained in combination with the phosphoric acid. Other methods and processes have been included without partiality, and the list is practically complete.

1830—SPRENGEL, C.
On the production of potash and alum from granite, gneiss and other rocks containing potassium silicate.
Erdm. Jour. Techn. Chemie, 1830, vol. 8, pp. 220-222.

CAMERON, F. K.
Waste and conservation of potash and phosphoric acid.
Jour. Ind. Engng. Chem., 1912, vol. IV, p. 169-172.

CHEM. FABRIK RHENANIA and A. MESSERSCHMIDT.
Utilization of natural rocks and process for obtaining alkalies by igniting rocks with lime.
German Pat. 264900, March 7, 1912.
Chem. Abst., 1914, vol. VIII, p. 219-220.

CHEM. FABRIK RHENANIA and A. MESSERSCHMIDT.
Process of working sulphate-containing caustic alkali liquors obtained from natural rocks.
German Pat. 268282, March 7, 1912.
Chem. Abst. 1914, vol. VIII, p. 1492.
J. Soc. Chem. Ind., vol. XXXI, no. 23, p. 1124.

COWLES, A. H., Sewaren, N. J.
Charge mixture for forming alkali silico-aluminate and hydrochloric acid.
U. S. Pat. 1040893, Oct. 8, 1912.

COWLES, A. H., Sewaren, N. J.
Process of forming a charge mixture for producing hydrochloric acid and alkali silico-aluminate.
U. S. Pat. 1040894, Oct. 8, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 23, p. 1124.

COWLES, A. H., Sewaren, N. J. Assignor to the Electric Smelting & Aluminium Company, Sewaren.
Process for producing hydrochloric acid and alkali silico-aluminates.
U. S. Pat. 1040977, Oct. 8, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 23, p. 1124.

COWLES, A. H., Lockport, N. Y.
Sodic silico-aluminate and hydrochloric acid.
U. S. Pat. 1041598, Oct. 5, 1912.
J. Ind. Engng. Chem., 1913, vol. V, p. 88.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 22, p. 1078.

COWLES, A. H., Sewaren, N. J., and A. KAYSER, Lockport. Assignors to the Electric Smelting & Aluminium Co., Lockport.
Process of manufacturing sodic silico-aluminate and hydrochloric acid.
U. S. Pat. 1041599, Oct. 15, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 22, p. 1078.

COWLES, A. H.
Process for the manufacture of hydrochloric acid and Na- or K-silico-aluminate.
British Pat. 19605, Aug. 27, 1912. French Pat. 448165, Sept. 11, 1912.
Chem. Abst., 1914, vol. VIII, p. 558.

COWLES, A. H.
Charge-mixture for the manufacture of hydrochloric acid and Na- or K-silico-aluminate consisting of an alkali chloride, C, and materials containing SiO_2 and Al_2O_3 which may contain some combined soda or potash.
British Pat. 19604, Aug. 27, 1912. French Pat. 448166, Sept. 11, 1912.
Chem. Abst., 1914, vol. VIII, p. 558.

CUSHMAN, A. S., and COGGESHALL, G. W.
The production of available potash from the natural silicates.
Paper read at joint meeting with the Eighth International Congress of Applied Chemistry, New York, Sept. 4-13, 1912. *Trans.*, vol. V, pp. 33-49.

Repr. *Trans. Amer. Inst. Chem. Engrs.*, 1912, vol. V, pp. 52-67.

J. Franklin Inst., 1912, vol. 174, pp. 663-678.
Chem. Engr., 1913, June, vol. XVII, pp. 221-227.

FOOTE, H. W., and SCHOLES, S. R.
The extraction of potash and alumina from feldspar.
J. Ind. Engng. Chem., 1912, vol. IV, p. 377.

HOFF, MAX M. Assignor to Th. L. Willson.
Process of obtaining alkali-metal compounds from minerals containing alkalies.
U. S. Pat. 1018186, Feb. 20, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 7, p. 334.

HAMBLOCH, A., and GELLÉRI, S.
Process for the decomposition of alkali-aluminium silicates such as feldspar.
German Pat. 258702, May 7, 1912. British Pat. 4842, Feb. 25, 1913.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 11, p. 602.

HART, E.
Potash, silica and alumina from feldspar.
Paper read at joint meeting with the Eighth International Congress of Applied Chemistry, New York City, Sept. 4-13, 1912.
(Repr.) *Trans. Amer. Inst. Chem. Engrs.*, 1912, vol. V, pp. 68-69.
J. Ind. Engng. Chem., 1912, Nov., vol. IV, pp. 827-828.

JUNGER, E. W.
Process of obtaining alkalis and hydraulic cement from rock materials, pure or Fe_2O_3-containing alkali-Al-silicates, such as feldspar, micas, clay schist.
British Pat. 28970, Dec. 16, 1912. German Pat. 283955, Nov. 6, 1912. French Pat. 453461, Nov. 15, 1912. Swedish Pat. 25427, Jan. 30, 1912.
Chem. Abst., 1914, vol. VIII, p. 232; 1492.

JUNGER, E. W.
Process for obtaining alkalis from alkali-ferrous minerals, such as feldspar, mica, etc.
British Pat. 26497, Nov. 18, 1912.
Chem. Abst., 1914, vol. VIII, p. 1548.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 10, p. 534.

LAWTON, CH. F., New York. Assignor to F. W. Huestis, New York.
Process of rendering mineral substances available as fertilizers by aid of fermentation.
U. S. Pat. 1029378, June 11, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 14, p. 698.

LINDBLAD, A. R.
Process of utilizing feldspar and like minerals.
German Pat. 266787, Oct. 20, 1912. British Pat. 23898, Oct. 19, 1912. U. S. Pat. 1083287, Jan. 6, 1914.
Chem. Abst., 1913, vol. VII, p. 2646.
J. Soc. Chem. Ind., vol. XXXII, no. 7, p. 364

MORSE, H. W., and SARGENT, L. W.
Process for obtaining soluble potassium compounds from feldspar.
U. S. Pat. 1041327, Oct. 15, 1912.
J. Ind. Engng. Chem., 1913, vol. V, p. 88.
Engng. Min. Jour., 1912, p. 1219.

NEIL, J. M., Toronto, Ontario.
Process of obtaining potash from feldspar.
U. S. Pat. 1034281, July 30, 1912. British Pat. 22557, Oct. 3, 1912. Canadian Pat. 150875, Oct. 7, 1913.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 17, p. 816.

PEACOCK, S. Assignor to American Acid Co., Baltimore.
Process of obtaining alumina and potash from feldspar.
U. S. Pat. 1035812, Aug. 13, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, p. 875.

PEACOCK, S. Assignor to American Acid Co., Baltimore.
Process for recovering silica, alumina and potash from feldspar.
U. S. Pat. 1030122, June 18, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 14, p. 686.

PEACOCK, S.
Process for obtaining alumina and potash from feldspar.
U. S. Pat. 1036897, Aug. 27, 1912.
J. Soc. Chem. Ind., 1912, vol. XXXI, no. 19, p. 922.

PEACOCK, B. Assignor to International Agricultural Corporation, New York.
Process of producing potassium hydrogen phosphate.
U. S. Pat. 1046327, Dec. 3, 1912.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 2, p. 85.

ROSS, W. H.
The extraction of potash from silicate rocks.
Orig. Com. Eighth Intern. Congress of Applied Chem., New York, Sept. 4-13, 1912. Sect. VII: Agric. Chem., vol. XV, pp. 217-229.
Amer. Fertilizer, 1912, Aug. 24, vol. XXXVII, pp. 44-48.
U. S. Dept. Agric., Bureau of Soils, *Circular* No. 71, July 16, 1912.

SCHNEIDER, P.
Process of recovering products rich in potassium from feldspar or the like K-silicates.
German Pat. 268865, Feb. 22, 1912. British Pat. 4403, Feb. 20, 1913. French Pat. 454632, Feb. 20, 1913.
Chem. Abst., 1914, vol. VIII, p. 1651.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 17, p. 867.

SCHOOT, F.
Recovering salts suitable for use as fertilizer from the waste gases from Portland cement furnaces.
German Pat. 291070, Nov. 13, 1912. U. S. Pat. 1064550, June 10, 1913.
Chem. Abst., 1917, vol. XI, no. 7, p. 881.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 14, p. 753.

WOLTERECK, H. C., and MOELLER, J.
Process for disintegrating silicates, especially mineral silicates.
German Pat. 261523, May 2, 1912.
Chem. Abst., 1913, vol. VII, p. 3211.

1913—BASSETT, H. P.
Process of obtaining K-compounds from feldspar.
U. S. Pat. 1072686, Sept. 9, 1913.
Chem. Abst., 1913, vol. VII, p. 3643.

BASSETT, H. P., Catonsville, Md.
Treatment of aluminium-bearing minerals for the manufacture of aluminium hydroxide.
U. S. Pat. 1079589, Nov. 25, 1913.
J. Soc. Chem. Ind., 1914, vol. XXXIII, no. 1, p. 23.

CHEM. FABRIK RHENANIA and A. MESSERSCHMIDT.
Fertilizers containing available potassium and phosphoric acid.
German Pat. 288089, Sept. 28, 1913.
Chem. Abst., 1915, vol. IX, p. 1819.

COWLES, A. H.
Cheaper alumina and aluminium from mineral silicates.
MET. & CHEM. ENG., 1913, vol. XI, pp. 140-143.
J. Ind. Engng. Chem., 1913, vol. V, no. 4, p. 331-335.

COWLES, A. H.
Alumina, hydrochloric acid, caustic alkalies and a white hydraulic cement by a new process from salt, clay and lime.
Diss. Eighth Intern. Congress Applied Chem., vol. XXVII, p. 35.
MET. & CHEM. ENG., 1913, vol. X, p. 695.

DITTLER, E.
The melting points of potassium-soda feldspars.
Tech. Min. Petr. Mittl., 1913, vol. 31, pp. 513-522.
Keram. Rundschau, 1913, vol. XXI, pp. 390-91.
Chem. Abst., 1914, vol. VIII, p. 222.

DOREMUS, C. A.
Process of making potassium sulphate.
U. S. Pat. 1054518, Feb. 25, 1913.

ELECTRIC SMELTING & ALUMINIUM CO.
Obtaining a fertilizer by igniting a mixture of tricalcium phosphate substances and materials containing alkali aluminium silicate.
German. Pat. 291495, Dec. 12, 1913.
Chem. Abst., 1917, vol. XI, p. 862.

ELECTRIC SMELTING & ALUMINIUM CO.
Manufacture of di-calcium phosphate.
French Pat. 454056, Feb. 6, 1913.
Chem. Abst., 1914, vol. VIII, p. 218.

ELECTRIC SMELTING & ALUMINIUM CO.
Manufacture of fertilizing products.
French Pat. 454336, Feb. 13, 1913. British Pat. 2485, Jan. 30, 1913.
Chem. Abst., 1914, vol. VIII, p. 396.

FRIEDENSBURG, F.
Extraction of potash from silicates.
Chem. Ind., 1913, vol. XXXVI, pp. 467-470.

GELLERI, S.
Process for recovering alkalis from silicate rocks (*e. g.*, orthoclase).
U. S. Pat. 1078495 and 1078496, both of Nov. 11, 1913.
Chem. Abst., 1914, vol. VIII, p. 405.

HANCOCK, W. C.
The extraction of potassium salts from silicate rocks.
Chem. World, 1913, vol. II, pp. 118-19.

HART, ED., Easton, Pa.
Process of making potash alum.
U. S. Pat. 1062278, May 20, 1913.

JUNGER, E. W.
Process for the simultaneous production of hydraulic cement and potassium in free or combined form.
Swiss Pat. 64425, Oct. 20, 1913.
Chem. Abst., 1914, vol. VIII, p. 2472.

LEEDEN, R. VAN DER.
Process for obtaining halogen compounds of alkalis, aluminium, silicon, titanium and other bases.
German Pat. 267867, Jan. 4, 1913. French Pat. 466721, Dec. 29, 1913.
J. Soc. Chem. Ind., 1914, vol. XXXIII, no. 17, p. 865.

MESSERSCHMIDT, A., Stolberg, Germany.
Method for extracting alkali metals in the form of nitrates from minerals.
U. S. Pat. 1076508, Oct. 21, 1913. (Same as German Pat. 252278, of 1911).

ROSS, W. H.
The extraction of potash from silicate rocks.
U. S. Dept. Agr., Bureau of Soils, Circular 71 (1913).
Chem Abst., 1913, vol. VII, p. 4035.

ROSS, W. H.
The decomposition of feldspar and its use in the fixation of atmospheric nitrogen.
J. Ind. Engng. Chem., 1913, vol. V, pp. 725-29.
Chem. Abst., 1913, vol. VII, p. 3643.
J. Soc. Chem. Ind., 1913, vol. XXXII, no. 19, p. 942.

SCHNEIDER, P.
Process for obtaining products rich in potassium from K-silicates, feldspar, etc.
French Pat. 454632, Feb. 20, 1913.
Chem. Abst., 1914, vol. VIII, p. 396.

SPLICHAL, J.
Decomposition of the feldspars.
Abhandl. Böhm. Akad., 1913, no. 12, pp. 1-20.
Neues Jahrb. Min. Geol., 1914, I, Ref., pp. 12-15.
Chem. Abst., 1914, vol. VIII, p. 1400.

THORPE, SIR ED.
A dictionary of applied chemistry.
1913, Longmans, Green & Co., vol. IV., p. 357.

TYDEN, S.
Hydrochloric acid soluble potash in phonolite, feldspar and lepolite.
Svensk Kem. Tidskrift, 1913, vol. XXV, pp. 146-152.
Chem. Abst., 1914, vol. VIII., pp. 193-194.

WILLSON, T. L., Ottawa, Canada.
Method of manufacturing double superphosphates.
British Pat. 25856, Nov. 11, 1913.
J. Soc. Chem. Ind., 1914, vol. XXXIII, no. 24, p. 1217.

1914—ANONYMOUS.
The preparation of potash from feldspar and other sources.
Chem. News, 1914, vol. CX, p. 175.
J. Soc. Chem. Ind., 1914, Oct. 31, vol. XXXIII, no. 20, p. 1007.

BASSETT, H. P.
Process for obtaining potash from feldspar.
U. S. Pats. 1091033 and 1091034, March 24, 1914.
Chem. Abst., 1914, vol. VIII, p. 1856.

BASSETT, H. P.
Process for obtaining soluble compounds such as alkali metal carbonates from clay, feldspar, granite or other aluminium-bearing material.
U. S. Pat. 1095306, May 5, 1914.
Chem. Abst., 1914, vol. VIII, p. 2228.
J. Soc. Chem. Ind., 1914, vol. XXXIII, no. 12, p. 644.

(To be concluded)

Synopsis of Recent Metallurgical and Chemical Literature

The German Chemical Industry.—*The Chemical Trade Journal and Chemical Engineer* (London) prints an interesting editorial in its Nov. 17, 1917, issue on recent developments in the large chemical companies in Germany. It is stated that a German report says that transactions on the Berlin Stock Exchange have recently been particularly active in shares of the companies engaged in the heavy chemical industry, with large upward movements in the quotations. In connection with this state of affairs rumors are in circulation to the effect that the question of largely increasing the share capital is engaging the attention of the leading concerns which entered into the enlarged community of interests in May, 1916, when the ordinary share capital of the three leading firms in the community—the Farbwerke Hochst, the Badische Anilin und Soda Fabrik, and the Farbenwerken vorm. Bayer & Co.—was rendered uniform on the basis of £2,700,000 each. No information appears to be forthcoming at present as to the projected capital augmentation, but it is considered probable that some such scheme is definitely proposed, having regard to the large extensions of the plants which are reported to have been carried out during the course of the war. A further factor in connection with the rumors is the statement that the present great community of interests is to be extended by the inclusion of other chemical firms.

The intention of the German Government to introduce compulsory syndicates, where such combinations do not exist and where voluntary efforts in this direction fail to accomplish the object in view, has now engaged the attention of the chemical industry. At the recent assembly of the Association for the Protection of the Interests of the Chemical Industry, which was held at Berlin, under the presidency of Dr. Hauser of Hochst, Dr. Riesser of Berlin, raised the question of the transition economy from war to peace work, and expressed his opposition to any compulsory syndicate in the chemical industry in that connection. If the central regulation of imports was inevitable, the chemical industry should be allowed to manage for itself and State limitation be restricted to supervision. It was necessary for freedom of trading to be restored to the fullest extent. The chemical firms, he said, desired to remain what they were—members of the creative class, without guardianship in their activity for the welfare of the country.

Effects of Heat on Celluloid.—The Bureau of Standards has recently issued Technologic Paper No. 98 by H. N. STOKES and H. C. P. WEBER on the effects of heat on celluloid and similar materials. The general conclusions from the work are as follows:

1. Celluloid (using the term in its popular sense to include the pyroxylin plastics in general) does not differ essentially from nitro-cellulose. The difference is one of degree and not of character. Nitrocellulose exists and reacts in celluloid as such; that is, as a solution of nitrocellulose in camphor or other solvent present, rather than as a new chemical compound. The admixture up to 20 per cent of zinc oxide does not decrease the rate of decomposition of the nitrocellulose in celluloid, the results seeming rather to show that there is an increase.

2. The decomposition of nitrocellulose in celluloid commences in the neighborhood of 100 deg. C. Above this tempertaure the heat of decomposition may raise the temperature of the mass to the ignition point, if loss of heat by radiation is prevented.

3. Above 170 deg. the decomposition of celluloid takes place with explosive violence, as with nitrocellulose.

4. The rate of combustion is five to ten times that of poplar, pine, or paper of the same dimensions and under the same conditions.

5. Celluloid articles may be ignited by momentary contact with bodies having a temperature of 430 deg. or above, i.e., temperatures below visible red heat.

6. In spite of wide differences between individual samples, no essential differences were found between the celluloids of American manufacture, nor between articles of American and foreign manufacture, nor between manufactured and unmanufactured articles.

7. The general qualities of celluloid as to stability may be best expressed by a time-temperature curve, taking the time necessary for exploding small samples at several temperatures, say 170 deg., 180 deg., 200 deg. and 220 deg.

8. The vapors evolved by decomposition are poisonous and extremely combustible and may be ignited by the heat of decomposition of the celluloid itself.

9. The decomposition of celluloid is autocatalytic, and while not necessarily explosive may readily approach that condition as a limit.

Chemically Pure Bismuth.—Bismuth at present is commercially manufactured with a purity of 99 per cent, and for all ordinary purposes this is sufficient. However, in the manufacture of electric and magnetic measuring instruments, for which bismuth is used in ever-increasing quantities, a much purer metal is required. M. MYLIUS and E. GROSCHUFF describe a very satisfactory process of refining bismuth, in the *Zeitschrift für Anorganische Chemie.*

The authors call attention to the fact that while a 99 per cent pure metal is obtained fairly easily, the remaining 1 per cent of impurities holds so tenaciously as to make its removal somewhat difficult. By heating the nitrate of bismuth, $Bi(NO_3)_3 + 5H_2O$, the oxide is formed and this can be reduced by hydrogen. The residue is melted and crystallized. The plan to purify bismuth by distillation does not work out in practice, as most of the impurities remaining after the ordinary refining process boil at a temperature of less than 1500 deg. Cent., which is the temperature of boiling bismuth.

The method described above is stated to yield a metal which does not contain more than 0.01 per cent of impurities and which melts at 271 deg. Cent. Wire of 1 mm. diameter has an electric resistance of 1.20 ohm. at 22 deg. If the percentage of impurities amounts to 0.1 per cent the resistance value is 3 ohms.

The Determination of Titanium in Ferro-Titanium.—An improved method of analyzing volumetrically the quantity of titanium in ferro-titanium has been discovered by G. ROEHL and described in the *Chemiker*

Zeitung. It is an improvement of the titration method evolved by Knecht and consists of the following operation: The strongly acid solution of ferro-titanium is reduced to a titanium chloride solution by the use of zinc and a current of CO_2. This reduced solution is then titrated with a hot solution of $FeCl_3$ in the presence of several drops of methylene blue. The color change is extraordinarily sensitive.

As the most satisfactory proportions the author recommends that 0.5 gram of the finely pulverized product be treated with 5 to 6 times its own weight of "Eschka alloy" to melt this mixture and then drop on it a very small quantity of water. Dissolve the whole by boiling in 200 cc. of concentrated hydrochloric acid. The solution is poured into a vessel of larger contents and water is added to make 500 cc., 100 cc. being used for each titration. To each 100 cc. is added 60-70 cc. of concentrated HCl and 4 or 5 zinc granules. A current of CO_2 is sent through the solution. When the reduction is complete the current of CO_2 is shut off, methylene blue added and the solution titrated with a hot solution of $FeCl_3$ of accurately known strength, tested on solutions of titanium oxide (TiO_2) prepared for that purpose.

Synthetic Rubber.—The Catalyst, official organ of the Philadelphia Section of the American Chemical Society, gives an abstract of an address delivered before the Section by Dr. FREDERICK DANNERTH of Newark, N. J., on the "Financial Prospects of Synthetic Rubber."

In his introductory remarks, Dr. Dannerth referred to the various attempts which have been made in England and America since 1909 to float companies for the manufacture of synthetic rubber. Many of these bore a close resemblance to stock-jobbing propositions. The only bona fide processes thus far recorded, and which actually demonstrated progress in the art, were those of the Synthetic Products Co. of England and the chemical works at Elberfeld and Ludwigshafen. The English company is at present handicapped by its overproduction of butyl alcohol, but if a new use were discovered for this material the process would at once become of exceptional interest.

Among the names prominently associated with the synthetic or laboratory production of rubber Dr. Dannerth mentioned those of Perkin, Harries, Matthews, Hofmann, Strange, Coutelle and Fernbach. Many more could be added to this list, but these are the men who have done much of the fundamental work. Mention was made of the fact that if the United States were suddenly cut off from its rubber supply it would cost the American rubber industry over $250,000 per day. Speaking of the raw materials required, he stated that the Strange-Fernbach process required starch, and this could be economically obtained from potatoes. An annual production of 10,000,000 lb. of rubber might require 500,000,000 lb. of potatoes grown on 50,000 acres of land. The starch is converted by fermentation into acetone and butyl alcohol. Another process which has been suggested is based on the use of aldehydes and ethyl alcohol. Such a process would, if rational, make it possible to utilize our liquor distilleries in case of national prohibition. A process developed by the Badische Company is based on the use of acetone. This would be of very great interest to us, as we are in a good position to produce calcium carbide. A company has, in fact, just been formed for manufacturing this material in Virginia. The acetylene yields acetic acid and acetone. The acetone yields, on further treatment, pinacone, dipropylene, and dipropylene rubber. At the wholesale price of four cents per pound, calcium carbide is one of the most attractive raw materials at the disposal of chemical manufacturers for the synthetic production of rubber. This fact was emphasized very strongly by Dr. Dannerth, and he indicated that this was at the present time the one process which should be given serious consideration by American chemists and investors.

The financial prospects of synthetic rubber will depend upon such factors as: The demand for rubber in the United States; the price that could be obtained for the product; the minimum price at which natural rubber can be sold in the United States; the competition which would be experienced from the natural product; the factory cost of the product; the particular process which is chosen; the extent of side products and waste products; the operation of incidental processes; the possibility of irregularities in the process; the ability to secure college-trained chemists and engineers; the price of the raw materials; the abundance of the raw materials; the regular supply of the raw materials; the protective action of an import tariff on crude rubber; the efficient conduct of the processes; the cost of labor and the choice of correct machinery and apparatus.

Reference was made to the fact that, according to a published statement in 1905, the Hoechst and Badische companies sold indigotin to dealers in Germany at 18 cents per pound. The total world-production of rubber in 1916, figured on a "washed and dried" basis, was estimated at 427,250,000 lb. In the same year the U. S. Customs House reported the total importation of all kinds of rubber at 267,000,000 lb.

Benzol as a Motor Fuel.—J. H. CLEGG of the Blackburn, England, Gas Company, recently presented some interesting data before the Manchester Gas Association on benzol recovery. According to the *Gas Record*, Dec. 12, 1917, Mr. Clegg thinks there will be a big demand for benzol after the war. In this connection the following remarks by Mr. Clegg as to the English situation are interesting:

"I think that it behooves every gasworks to install a benzol plant, apart from patriotic reasons, as I venture to anticipate a great demand for this production as a power fuel, in spite of the fact that gas will undoubtedly retain the field which it is now obtaining as a propellant of motor vehicles. Even compressed gas in cylinders is scarcely adaptable or safe for motorcycles, of which there will be an enormous surplus at the conclusion of the war. Aeroplanes and airships will not by then be conveyances of the future, but will be well in evidence. Let us then aim to grasp the whole field of transport, either by gas, coke, or benzol. I have found by personal experience that benzol is more efficient than petrol, if the sulphur impurities are removed, and that the statement that the former coagulates the lubricating oil is not justified if a good quality oil is used. As for the cost of production, we know we can produce this commodity to compete favorably with petrol, for whatever the conditions existing for importation and distribution of the latter, like advantages or disadvantages apply to ourselves."

Recent Metallurgical and Chemical Patents

Coal-Tar Products

Production of Phenol.—HERBERT S. KIMBALL of Newton, Mass., patents a process of making phenol from benzol by a cyclical process. The patent is assigned to the Merrimac Chemical Co. of Boston, Mass. A complete cycle embodying the invention is shown on the accompanying diagram.

The present invention may be carried out as follows: The benzol is first sulphonated as usual, and the resulting sulphonic acid compound, containing an excess of sulphuric acid, is wholly or partly neutralized by calcium sulphite, utilizing for this purpose the calcium sulphite which is produced at a later stage of the cyclical process, as explained below. The neutralization is effected in closed tanks, and the evolved sulphur dioxide, or such portion thereof that may be required, is employed to decompose the sodium phenolate, as described in the above mentioned application. In case the quantity of calcium sulphite available is insufficient for complete neutralization of the sulphonic acid compound, it is supplemented by lime or limestone.

The calcium benzol sulphonate prepared as above is treated with the molecular equivalent of sodium sulphite, and is thereby transformed into sodium benzol sulphonate. The sodium sulphite may be introduced either in solution or in solid form into the solution of calcium benzol sulphonate, and the calcium sulphite which separates out is applied toward the neutralization of the sulphonic acid compound produced in the first step of the process.

The sodium benzol sulphonate is now subjected to a caustic fusion to produce sodium phenolate, which in turn is decomposed by sulphur dioxide (undiluted) arising from the neutralization step of the process. The phenol is decanted, and the remaining liquor, containing sodium sulphite or bisulphite, or a mixture of these, is utilized in part for the conversion of the calcium benzol sulphonate into the corresponding sodium salt, as above described, and is in part causticized by lime, yielding a dilute caustic soda solution and calcium sulphite, the latter available for neutralizing the benzol sulphonic acid. If desired, the caustic soda solution may be concentrated and returned to the cycle. (1,245,353, Nov. 6, 1917.)

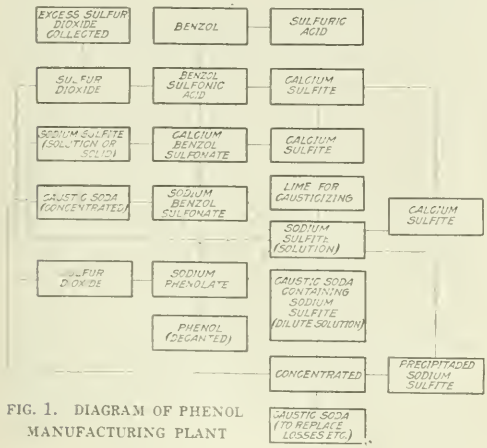

FIG. 1. DIAGRAM OF PHENOL MANUFACTURING PLANT

Production of Phenol.—In a patent granted to HENRY HOWARD of Brookline, Mass., the sodium phenolate prepared as usual by the caustic fusion of the sulphonic body, is decomposed by sodium bicarbonate, preferably employed in the proportions required to transform all of the sodium, whether present as phenolate or as caustic soda associated with the phenolate, into normal sodium carbonate. Under these conditions the reaction is stated to be very rapid, and even practically instantaneous. The reaction will proceed at normal and higher temperatures, and is exothermic; 60 deg. C. is a satisfactory operating temperature, although either higher or lower temperatures may be used. There are no fixed upper or lower limits for the concentration of the phenolate solution, but a concentration in the neighborhood of 23 deg. Baumé is satisfactory in practice. To avoid unnecessary dilution, the bicarbonate may be added to such solutions in solid form, although this is not essential. Most of the phenol rises to the surface of the liquid, and may be separated by decantation, the remainder being recovered from the carbonate solution in any appropriate way, as, for instance, by distillation, or by blowing steam through the liquid. About one-half, or somewhat less, of the sodium carbonate solution produced as above, is now treated in any suitable apparatus with the lime-kiln gas, and is thereby reconverted into sodium bicarbonate, which is used for the treatment of another batch of sodium phenolate. The remainder of the sodium carbonate solution is causticized by lime, and may be concentrated for re-use in the preparation of the phenolate, or applied to any other purpose. (1,245,343, Nov. 6, 1917.)

Miscellaneous Chemical Processes

Paraffin Ethers.—The manufacture of paraffin ethers such as ethyl ether is the subject of a patent of BURRITT S. LACY of Sewaren, N. J., assigned to the Roessler & Hasslacher Chemical Co. of New York. The following reactions illustrate the manufacture of ethyl ether:

$$(1)\quad C_2H_6 + Cl_2 = C_2H_5Cl + HCl$$
$$(2)\quad 2C_2H_5Cl + CaO = (C_2H_5)_2O + CaCl_2$$

It was found that under certain conditions the formation of ethers as exemplified by reaction (2) may be sucessfully carried out and with nearly quantitative yields. In connection with this fact it was found especially in working on a large scale, that the highly exothermic character of reaction (2) presents a serious difficulty due to the tendency to rapid decomposition and carbonization brought about by the heat of reaction itself. It was furthermore found, however, that this unfavorable heat evolution may be wholly neutralized and the reaction made entirely successful even on a large scale by means of admixture with the ethyl chloride of a large amount of an inert gas.

Any one of a number of inert gases, for example nitrogen or methane may be employed, but it is preferable to use the excess C_2H_6, which is already present with the C_2H_5Cl when prepared according to reaction (1) as described in copending application Serial No. 852,164 filed July 21, 1914, for the manufacture of ethyl

chloride since the process then becomes a continuous cycle with production of substantially only HCl, ethyl ether, and $CaCl_2$, without the necessity of first separating the C_2H_5Cl as such.—(1,245,742, Nov. 6, 1917.)

Salt Cake and Nitre Cake in Making Silicofluoride.—KARL F. STAHL, of Pittsburgh, Pa., patents a process of treating phosphate rock for the production of sodium silicofluoride from the fluorine and silicic acid contained. Phosphate rock contains some flourine as calcium fluoride and silicic acid either free as silica, or combined as silicates. In the process of making acid phosphate for use as a fertilizer the ground phosphate rock is mixed with sulphuric acid which has previously been diluted to the required strength. This converts the tertiary calcium phosphate into primary phosphate, rendering it soluble in water, but it also liberates the flourine of the calcium fluoride, forming hydrofluoric acid. This acid in turn combines with the silica forming principally silicon fluoride (SiF_4), which, as a gas, escapes into the air and is detrimental to surrounding property. In order to prevent the escape of this gas, the silicon fluoride is brought into contact, in suitable apparatus, with sprays of water, and this decomposes the silicon fluoride into hydrofluosilicic acid and silicic acid according to the equation:

$$3SiF_4+3H_2O=2H_2SiF_6+H_2SiO_3$$

The hydrofluosilicic acid is immediately absorbed in the water in which the silicic acid remains suspended. The two are separated by means of a filter press and the hydrofluosilicic acid is converted into sodium silicofluoride, a useful product, by means of a solution of sodium chloride, according to the equation:

$$H_2SiF_6+2NaCl=Na_2SiF_6+2HCl.$$

This leaves a weak solution of hydrochloric acid which is of little value and cannot be utilized in the process. In locations where there is no large body of water it is necessary to make some arrangements for the disposal of this weak solution of hydrochloric acid which is produced in considerable quantity. This problem becomes very difficult in some cases and practically prohibits the erection of a plant for the production of sodium silicofluoride where such plant would otherwise be most favorably situated.

One of the objects of the present invention is to provide an improved process for treating phosphate rock in which resulting products of value or ones which may be easily disposed of are produced. Another object is to provide an improved process for treating phosphate rock in which the product resulting from the conversion of hydrofluosilicic acid into sodium silicofluoride may be utilized in the process of treating the rock.

The phosphate rock, according to the improved process, is treated with sulphuric acid which renders the phosphate soluble in water and produces hydrofluoric acid. This acid combines with the silica, forming principally silicon fluoride (SiF_4), which afterward is decomposed into silicic acid and hydrofluosilicic acid and this latter acid is then absorbed in water. Instead of treating this solution with sodium chloride, it is treated with a solution of sodium sulphate which precipitates sodium silicofluoride according to the following equation:

$$H_2SiF_6+Na_2SO_4=Na_2SiF_6+H_2SO_4$$

The sodium silicofluoride is sparsely soluble in water or in dilute sulphuric acid, and consequently is thrown down as a fine powder or sludge, which is separated from the liquid by a suitable filtering device, such as a filter press or centrifugal machine. It is then washed free of acid, dried and ground, whereupon it is ready for shipment.

The dilute sulphuric acid which is produced by this reaction may be utilized in the process of treating the phosphate rock so that no provision need be made for the disposition of large quantities of waste acid liquid. For the purpose of acidulating the phosphate rock in the initial reaction sulphuric acid of 50 deg. Baumé, is generally used. In the usual chamber process of making sulphuric acid the latter is usually produced stronger than 50 deg. Baumé and to use it for acidulating phosphate rock it is diluted with water to reduce its strength. In the present process, instead of diluting this acid with water, it is diluted with the sulphuric acid solution obtained in the final stage of the process. Such solution generally contains sulphuric acid in a dilute state of about 7 deg. Baumé. The acid solution resulting from the process is thus not only disposed of but it is utilized in the treatment of the phosphate rock. Sodium sulphate and acid sulphate may be obtained in the form of salt cake and nitre cake respectively, which are waste products from the manufacture of hydrochloric and nitric acid. They are relatively inexpensive and often contain some free sulphuric acid. In such case more sulphuric acid or a stronger acid is obtained in the final stage of the process which may be used in treating the rock. The process thus enables the waste cake from the nitric or hydrochloric acid process to be used. In addition to disposing of the waste products from these acid processes, the use of such products in treating phosphate rock produces a resulting acid solution which may be again used in the initial step of treating the rock. The waste products of two processes are thus saved and the difficulty of disposing of them avoided. The sulphuric acid does not affect the apparatus for handling the precipitated sodium silicofluoride to as great an extent as the hydrochloric acid heretofore produced and therefore it is claimed renders the process more inexpensive by reason of the reduction in the replacements of apparatus. (1,247,165, Nov. 20, 1917.)

Acetaldehyde from Acetylene.—It is well known that acetylene may be caused to unite with the elements of water, yielding acetaldehyde, by bringing it into contact with a suitable compound of mercury in the presence of sulphuric acid. HAROLD HIBBERT of Pittsburgh, Pa., patents an improvement on processes of this general character and assigns same to the Union Carbide Co., of New York City.

According to the invention, acetylene is led into an acid bath of the general character above mentioned, in material excess of the amount which can be absorbed in the first reaction. The bath is preferably maintained at a temperature of 70 deg.—80 deg. C., whereby the bulk of the acetaldehyde formed is continuously distilled off, mixed with the excess of acetylene. These mixed gases are conveyed directly to a second acid bath, preferably having the same characteristics as the first, where a further reaction takes place. If desired, the commingled gases from this second bath, which by

reason of the further reaction will contain a proportionately smaller amount of acetylene, may be conveyed to a third bath, and so on to any desired number of series-connected baths. Ultimately a sufficiently complete absorption of acetylene, for example an absorption in excess of 75 per cent of the original volume, is secured. The exit gases from the final bath, consisting predominantly or substantially of acetaldehyde, are led to a condensing system, from which any residual acetylene may be returned to the first element of the absorption system, together with sufficient added acetylene to re-establish the desired excess. The rate of supply of acetylene to the system will depend upon several factors, including the number of vessels in series, the volume of the acid baths, and their conversion efficiency. Usually it is preferred to supply acetylene at such rate that some 50 per cent, more or less, of the gas entering the first absorption vessel will pass therefrom to the next in series. (1,247,270, Nov. 20, 1917.)

Iron and Steel

Sintering Ores.—A continuous sintering process for sintering fine ores, concentrates, etc., is patented by JAMES GAYLEY of New York City. The apparatus can be applied to lean magnetic ores containing from 30 to 40 per cent of iron and which are too fine for direct use when concentrated. Large scale operations are necessary in order to be profitable. One of the features of the present process is the possibility of treating layers several feet thick, whereas formerly only about 7 in. thickness could be treated on a continuous machine. The sides of the cars may be of any height desired and the number of idle cars is greatly reduced. In general the process consists in the employment of two parallel tracks, in substantially the same horizontal plane, over which the cars are adapted to be moved uniformly and continuously in reverse directions. Having reached the discharge end of a track each car is emptied of its sintered contents, transferred in any suitable manner to the return track, refilled with ore or other material, which is then ignited and sintered during the passage of the car to its original starting point, where it is again dumped, refilled and caused to travel in the reverse direction over the first track. Some of the advantages of the process as given in the patent specification are as follows:

"By far the largest proportion of materials which are sintered at the present time by the continuous process, rarely require for the best operative results a depth or layer in excess of 9 in., consequently, the sides of the cars or pallets are made low, and they *have no upright ends at all.* The cars are also carried on wheels that run on the tracks provided for that purpose, and at both ends they are so constructed or planed off that they will make tight joints when brought together in a train to prevent the leakage of air. It is further usual to provide on the sides of the cars wind seals, preferably composed of single bars free to move vertically in a slot in the car body and slide over the edges of the wind box. In the process of sintering herein described the cars are always held in an upright position, so that this or many other forms of wind seal may easily be applied and used.

"The advantage of using cars without upright ends follows from the fact that this provides for the operation being carried on as a strictly continuous one. The several cars are dependent in the sense that their ends contact to make close air-tight joints throughout the sintering train. The layer of sintering material which such cars support is, moreover, continuous, or uninterrupted throughout the sintering period. From this it results that the ignition of the layer is more uniformly and effectively performed, and carried out while the cars are in motion. When independent cars with side and end walls are used the ignition of the charge takes place under a hood, the cars having the side and end walls of equal height to prevent leakage of the ignition flame, and it is required that each car remain stationary while the ignition of its charge is taking place.

"These stoppages of each car, in turn, stop the whole train and thereby render the process an intermittent one, curtailing the sintered output and imposing a variable load upon the suction fans through the variations in the percentage of the total sintering bed from time to time, thus producing at different times a variable suction pressure in different parts of the same, but disconnected sintering bed.

"The material which lies against the sides and ends of independent cars is, moreover, not so perfectly ignited, so that the elimination of ends reduces the area of imperfect ignition. Besides, the car with side and end walls makes the sintering layer disconnected, and it is not practicable to properly ignite a moving layer which may vary considerably in depth. For effective and economical ignition, the igniter must be close to the moving layer to produce the required heat concentration, but if for any reason a change occurs in the character of the material to be sintered, and a varying depth of the layer is required, it is not possible with independent cars to properly adjust the height of the igniter above the layer, as this is limited by the ends of the cars which must pass under the igniter, and in consequence the ignition and sintering of the layer is imperfect.

"In treating the same kind of material in a connected or continuous layer, the igniter can be placed in a fixed and proper position for that material and remain in such position, and this fact permits the use of a gas of low calorific power such as blast furnace gas, while intermittent ignition under a hood requires a high calorific and much more expensive gas.

"In sintering operations where independent cars are used and the charges ignited under a hood, the charging of the cars and the ignition of the material become manual and intermittent operations, whereas in the method or process as herein described, the only manual operations involved are the dumping and the transferring of the cars." (1,247,661 Nov. 27, 1917.)

Dolomite Refractory Brick.—JAMES O. HANDY and ROBERT M. ISHAM of Pittsburgh, Pa., patented a dolomite refractory brick and process of making same. The patent is assigned to the Allen S. Davison Company of Pittsburgh, Pa. In granulating calcined dolomite for making refractories for basic open hearth furnaces, considerable dust and fine material are produced. In the present patent it is proposed to use this dust for producing refractories, either alone or in mixture with other material. This waste dolomite is dead burned as it comes, and is afterward submitted to a brick-making treatment and another dead burning, producing strong, dense and refractory bricks. It is stated that they show no tendency to slack when placed in boiling water. For burning it is a matter of convenience to add more or less water to the dust to ball it up and form aggregates which can be handled in a rotary kiln; a rotary kiln being well adapted for this first burning. No other treatment is necessary. (1,248,486, Dec. 4, 1917.)

Rust-Proofing Iron and Steel.—A process of rust-proofing using vapors containing phosphorus compounds is patented by WILLIAM H. ALLEN of Detroit, Mich. The process consists in subjecting articles of iron and steel, properly cleaned by pickling or sand blast, to the fumes or vapors of phosphorus pentoxide or anhydride together with some aqueous vapor until surfaces of basic phosphates of iron are produced. These vapors may be produced in any desired manner, the preferred process consisting in subjecting a mixture of ground phosphate rock, coke and sand to a strong current in an electric furnace. The liberated phosphorus immediately changes to P_2O_5, and these fumes are drawn into the processing chamber by means of a suction fan. The fumes may be first passed through a dust chamber. (1,248,053, Nov. 27, 1917.)

Temperature Regulator.—PORTER H. BRACE of Pittsburgh, Pa., patents a regulating device which is particularly applicable to the regulation of heat treating, motor speeds, pressure in tanks, etc. The patent is assigned to the Westinghouse Electric & Manufacturing Company. The apparatus includes a potentiometer conductor, a thermo-couple or generator that is subjected to the temperature of the device, the temperature of which is to be regulated or that is actuated in accordance with other varying conditions, such as speed, pressure or energy, and a galvanometer for controlling the operation of a potential regulator or other regulating device. The galvanometer is connected in series with the thermo-couple or generator, and the circuit, thus constituted, is connected to the potentiometer conductor. A periodically actuated cam device having a contour corresponding to the desired time-temperature or other predetermined curve is adapted to so change the connections of the series-connected circuit, with respect to the potentiometer conductor, that the galvanometer is adapted to control the potential regulator or other regulating device to cause the temperature, pressure, speed or energy to vary in accordance with the predetermined desired characteristics. (1,248,444, Dec. 4, 1917.)

New Holder for Drawings and Blue Prints

The accompanying photographs show a new holder for drawings, blue prints, specifications, etc., made by the National Company, 273 Congress Street, Boston, Mass. Fig. 1 shows the lock which is used for

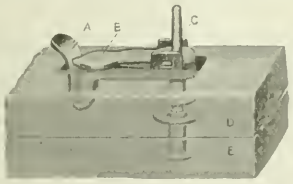

FIG. 1

holding the sheets and Fig. 2 shows the top string of the binder removed and print being taken from or added to file as desired. Referring to Fig. 1, the binder is locked by pressing on A. To release the

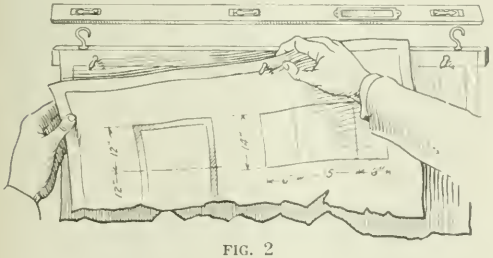

FIG. 2

binder the tongue B is pressed. This locks or releases B on hardened stud C, which is fastened into lower strip of oak-wood binder E.

The holder has a removable index card and will hold from one to sixty prints, without tearing or soiling.

Improved Quartz Mercury-Vapor Lamp for Ultra-Violet Light

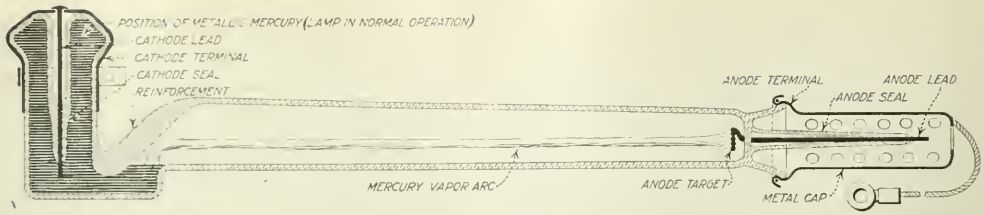
THE photochemical activity of invisible light waves existing beyond the visible violet of the spectrum has long been a recognized fact, and considerable research has been done to determine the nature and extent of the reactions produced. The shortest wave length of light perceptible to the eye is about .3969μ, in the violet end of the spectrum. Rays of shorter wave-length vary in their activity and effect. Berthelot divided them into four groups: 1. Wave lengths 0.4 to 0.3μ, comprising the ultra-violet rays that reach the earth's surface in sunlight. These rays are similar to the violet rays of the visible spectrum. 2. Wave lengths 0.3 to 0.2μ, medium rays of strong photochemical effect, producing marked chemical and physical changes. 3. Wave lengths 0.2 to 0.15μ, useful in synthetic processes. 4. Wave lengths 0.15 to 0.1μ, comprising an ultra-violet region about which little is known.

Among the physical and chemical effects produced by ultra-violet light are many of practical value, affording quick tests for certain properties, and acceleration of certain chemical reactions. The sterilization of liquids such as water and milk, and of semi-solids like edible fats, is readily accomplished by ultra-violet rays. Exposure of only a fraction of a second under proper conditions is required for complete sterilization. Most dyes fade rapidly under treatment with ultra-violet light, and some remain fast. Fabrics like cotton, rubber, oil-cloth, etc., reveal in a comparatively few minutes the deterioration that otherwise would not become apparent for days in ordinary light. Numerous organic substances are bleached by its action.

Chemical reactions produced by ultra-violet light are many and varied. Chlorine derivatives of toluol are produced in greatly increased yields and without undesirable by-products if the reaction proceeds in the presence of ultra-violet rays. Other chlor-substitution organic products are formed with greater facility, in greater quantity and of higher degree of purity if ultra-violet light enters into the reaction. The halogen elements generally seem sensitive to this force and enter into synthetic reactions rapidly under its influence. Cyanogen is converted into para-cyanogen, sulphur and phosphorus show allotropism, organic compounds undergo isomeric changes, hydrolytic reactions are accelerated, and numerous other changes occur under influence of ultra-violet rays.

The production of these rays in a manner suitable for application in the arts has been the subject of considerable invention. They are given off in concentrated form from a mercury-vapor lamp, but since glass is impervious to them it is necessary to construct the lamp of quartz if the rays are to be used.

An improved form of quartz mercury-vapor lamp which embodies new features in construction and application is manufactured by the R. U. V. Company, New York City. This lamp produces an ultra-violet component several times stronger than that yielded by other forms of quartz mercury-vapor lamps. The wave lengths of its light have been measured as low as 0.18μ, indicating a high degree of activity according to Berthelot's classification given above.



IMPROVED LAMP FOR ULTRA-VIOLET RAYS

The shape of the lamp is shown in the accompanying drawing. It consists principally of an exceptionally clear crystal-quartz frame containing mercury, fitted at each end with terminals and provided with an unusually high vacuum. The cathode terminal of the lamp under running conditions contains practically all of the mercury, as the pressure built up in the luminous tube forces the mercury back into the cathode end. The anode end is fitted with a tungsten terminal that is refined to a point approaching 100 per cent purity in order to prevent discoloration of the luminous tube.

The seals consist of tungsten wire sealed to the tube by means of a graduated mixture of glass and quartz, so distributed as to present approximately 100 per cent quartz nearest to the luminous tube and 100 per cent glass at the outside end of the seal. This combination of glass and quartz provides proper coefficient of expansion to prevent loss of vacuum.

The luminous tube or that part of the lamp in which ultra-violet rays are radiated, extends from the reinforcement bend near the cathode end to the tungsten coil forming the anode terminal, and therefore presents a radiating distance approximately 6 in. long.

This type of lamp is known as the "hot anode" type and differs from all other designs in that no mercury chamber is used at the anode end. This feature permits of operation of the lamp in any plane from vertical to horizontal, and therefore permits of application to practically any form of equipment used by the chemical manufacturer.

The metal cap fastened to the anode end, and attached directly to a collar at the end of the luminous tube, prevents the anode seal from mechanical injury and provides as well a means for attaching the positive lead wire in such a way as to remove strain from the anode seal. The negative seal is protected from strain by soldering it with silver to a strap which passes over the top of the cathode end. It is held rigidly in place by a circular band fastened around the vertical bulb of the cathode end.

The cathode end of the luminous tube is reinforced with thick quartz to absorb the shock of the mercury-vapor arc which strikes against it, while the other end of the mercury-vapor arc terminates against the target formed by the coil of tungsten wire which is the anode terminal. It is considered that the angle presented by the reinforcement of the luminous tube to the mercury-vapor arc, is such as to reflect back into the luminous tube some ultra-violet light that otherwise would escape.

To start the lamp the luminous tube is placed in a horizontal plane which permits the flow of mercury across it, so connecting the anode and cathode terminals, and immediately after the current is supplied to the lamp the anode terminal is tilted upward to strike or draw an arc. In a short time thereafter sufficient temperature and pressure is built up inside the luminous tube to produce the maximum amount of ultra-violet of which the lamp is capable.

To support this mercury-vapor arc, as in the case of all mercury-vapor arcs, ballast resistance is required, and such resistance is placed in series. When the lamp is started cold, about 20 ohms resistance is placed in series, but when the lamp is normally operating, one-half of this resistance is cut out so that normally 10 ohms is constantly in series with the lamp terminals. This cutting out of resistance is accomplished automatically on a small switchboard that is provided as an accessory to the lamp.

The starting characteristics of the lamp are therefore 8.5 amp. at 220 volts D.C., which is required normally for 10 to 15 min. As soon as the starting resistance of 10 ohms is cut out, the lamp, then being in normal running condition, consumes 3.5 amp. at 220 volts D.C.

Insulation Test on Steam Drums

An interesting test for determining loss of heat by radiation from boiler settings and steam drums was recently made by Mr. C. A. Eastwood, Superintendent of Station A, Pacific Gas and Electric Company, San Francisco, Cal. For his experiment Mr. Eastwood selected a 560-h.p. B. & W. boiler, the steam drums of which were covered with one course of common brick. A rectangular can containing a measured quantity of water was placed on top of one drum and the boiler was run at its rated capacity for a period of three days. During this time the rise in temperature of the water was carefully noted, and with these data it was a comparatively simple matter to determine: (a) the amount of heat radiated per square foot of surface per hour; (b) the amount of heat radiated from the total exposed area of the drums, and (c) the quantity of fuel which was being burned to make up for this loss. Mr. Eastwood's figures showed that the loss totaled 390 barrels of oil per year.

To determine how much of this fuel-loss could be saved by the use of an effective heat insulating material, one 2½-in. course of nonpareil insulating brick (Armstrong Cork & Insulation Company, Pittsburgh, Pa.) was then placed on top of the common brick covering, and readings were taken as in preceding tests. The result showed that with the nonpareil brick in place the loss of heat amounted to only 144 barrels of oil per year. With oil costing 70 cents per barrel, the saving amounted to more than enough to pay for the cost of the insulating brick and the labor required for installing them.

The total amount of heat lost represents that radiated from the steam drums alone. Had the radiation from the exposed boiler walls been included as well, the total heat-loss would have been greatly increased. Furthermore, if the common brick had been removed entirely and replaced with a coarse nonpareil brick set on edge, giving 4½ in. of insulation instead of 2½ in., a still greater saving would have been effected, since, according to the manufacturers, nonpareil brick are ten times better heat insulators than either common brick or fire brick.

Personal

MR. L. DOUGLAS ANDERSON, superintendent of the Midvale, Utah, smeltery of the United States Smelting Co., has been appointed manager of smelteries for the company at Salt Lake City, Utah. The company is a subsidiary of the United States Smelting, Refining and Mining Company.

MR. H. A. BAKER, chief chemist of the American Can Co., has gone to Washington to act on the committee on conservation of tin plate.

Professor CHARLES BASKERVILLE, Professor of Chemistry and Director of Laboratories of the College of the City of New York, delivered a lecture at the Royal Canadian Institute, Toronto, Canada, December 8th, the subject being, The Hydrogenation of Vegetable Oils.

MR. WARREN F. BLEECKER, of Boulder, Colo., spent a few days in New York during Christmas week.

MR. C. L. BRICKMAN was recently appointed chief chemist by the Rex-Hide Rubber Manufacturing Company, East Brady, Pennsylvania. Mr. Brickman comes from the Research and Development Laboratories of the U. S. Rubber Company.

Mr. E. J. CARLYLE and Mr. M. R. HULL have recently returned from Russia. Mr. Carlyle is manager and Mr. Hull, engineer, of the Sissert Mining Company, which operates a large concession in the Ural Mountains, near Ekaterinberg, mining and smelting copper ores. While the property was still operating at the time of their departure, the management had been assumed by committees of workmen, in accordance with their ideas of freedom. Messrs. Carlyle and Hull expect to make Salt Lake City their headquarters for some time.

Mr. A. E. DRUCKER is in Baltimore supervising the construction and starting of a concentrator mill.

Mr. ALFRED D. FLINN, deputy engineer of the Board of Water Supply, New York City, has been elected secretary of the Engineering Council, secretary of the Engineering Foundation, and secretary of the United Engineering Society. The Engineering Council was formed early in the fall of 1917, and its organization was described in our issue of Sept. 15, 1917. The United Engineering Society is the governing board of the Engineering Societies Building into which the Civil Engineers recently moved, and the Engineering Foundation is the founder organization of the societies which originally combined into the one organization. Thus all these activities will center in one man.

Mr. L. F. S. HOLLAND, lately field engineer for the Consolidated Arizona Smelting Co., Humboldt, has been appointed consulting engineer to the Arizona Mines & Reduction Co., Wickenburg, Arizona.

Mr. D. C. JACKLING, of San Francisco, has been placed in charge of building the Government's explosive plants. He will act under authority of the Secretary of War, by whom he was appointed. There is contemplated the expenditure of more than $90,000,000 in the erection of explosive plants for the Government, in order to supplement the present output of private manufacturers which it is calculated will not be sufficient to meet the Government's future needs.

Mr. E. F. LAKE, metallurgical engineer, formerly located in Detroit, Mich., has taken the position of assistant superintendent of the Rich Tool Co. The company is manufacturing one-piece valves from high-speed steel for airplane and automobile engines. It is also making valves from a high chromium steel similar to the stainless steel recently placed on the market.

Mr. R. A. LEAHY, formerly on the research staff of the Anaconda Copper Mining Co., has joined the Royal Flying Corps, and is now at Toronto, Ontario, Canada.

Dr. GILBERT N. LEWIS, of the University of California, has recently received a commission as major in the gas service. He will go abroad.

The Hon. SIR CHARLES PARSONS, member of the Council of the Institute of Metals (London), is to give the eighth annual May lecture before the Institute of Metals next spring. The lecturer will deal with the subject of the formation of artificial diamonds, which he has been experimenting upon for over thirty years.

Mr. ROBERT K. TOMLIN, JR., managing editor of *Engineering News-Record*, sailed recently for France to serve *Engineering News-Record* and the other McGraw-Hill engineering publications as special correspondent at the front.

Prof. WM. H. WALKER, head of the chemical engineering department of Massachusetts Institute of Technology has been commissioned lieutenant-colonel in the Chemical Corps, U. S. A., a newly created branch of the war department. He will have charge of co-ordinating the chemical activity in this country while Dr. Raymond F. Bacon, of Mellon Institute, Pittsburgh, will be engaged in the same capacity in France.

Obituary

DR. HUGO SCHWEITZER, the well known chemist and dye expert, passed away Dec. 23, at his home 410 Riverside Drive, New York City. He was head of the Synthetic Patents Co., 117 Hudson Street, New York City, and had a long experience in dyestuffs and organic chemistry. He was born in Germany in 1861 and received his degree at the University of Freiburg. He was successively chemist for the Badische Anilin and Soda Fabrik, Ludwigshafen, and the Farbenfabriken, formerly Fr. Bayer Co., Elberfeld. After he came to this country he became an American citizen and was past secretary of the New York Section of the Society of Chemical Industry and ex-president of the Chemists' Club.

Book Reviews

PRACTICAL PYROMETRY. By *E. S. Ferry, G. A. Shook* and *J. R. Collins*. Duodecima (14 x 20 cm.), 147 pages, 73 illustrations. Price, $1.50. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd.

An elaboration of notes compiled for a student laboratory course in Purdue University. After a short introductory chapter on temperature scales, the other four chapters deal with resistance, thermoelectric, radiation and optical pyrometry respectively. These are well presented, with many good experiments to teach the basic principles on which they act. Other forms of pyrometry than these four are *practical*, however, and are not considered. The book is to this extent defective. The English is poor at places, and scientific terms carelessly or inaccurately used at times. We cannot agree with the statement that iron, steel and nickel become brittle at about 700 deg. C. (p. 27). The book is pretty good, with some weak features, like those noted.

METALLURGICAL CALCULATIONS. Part I: Chemical and Thermal Principles. By *J. W. Richards*. Fourth Edition, revised and enlarged. Octavo, 238 pages. Price, $2.00. New York: McGraw-Hill Book Company. London: Hill Publishing Co., Ltd.

Since the first edition of this work was published, in 1906, it has become so widely used and known that further cataloging of its contents is unnecessary excepting a notation of the improvements in this last edition. The valuable thermo-

chemical tables have been brought up to date, and arranged in a better form; the tables of thermophysics of the elements have been greatly extended, to include heats of fusion and vaporization and vapor tensions of the elements; the thermophysics of chemical compounds have been amplified; the table of thermal emissivity has been lengthened by recently determined data. This fourth edition should therefore be much more valuable to the metallurgist and engineer than the preceding editions. By an unfortunate error (page 100), the total heat in mercury at its boiling point is given as 117 instead of 11.7, which changes the heat in the vapor at the boiling point to 79.5 and at the critical point to 100.

The publishers inform us that they contemplate issuing a one-volume edition of all three parts of Dr. Richards' work. It may not be generally known that these calculations have been translated into Russian, Italian and German, and that translations into French and Spanish were begun, but have been interrupted by the war. This is an enviable record of the general appreciation of these books by technologists in all parts of the world.

EVERYMAN'S CHEMISTRY. By *Ellwood Hendrick.* Octavo, 374 pages. Price, $2 net. New York: Harper and Brothers.

This is a book in which the author sits down with you and converses delightfully on the "ways of stuff," in an effort to convey to the average man a sense of the importance of chemistry in modern life. If he catches your interest lagging or your eye wandering, he promptly recovers your attention by opening a new view of the subject. Those who have thought of chemistry as though it were spelled "chemystery" will find here an easy comprehension of the elements of the subject that will lead them on to deeper study. Being a man of imagination, the author resorts to many forms of imagery in order to convey his subject clearly and interestingly to the reader. He frequently resorts to analogy between the "ways of stuff" and the characteristics of people to show why materials act as they do. Thus, among the "red-headed halogens" we find fluorine to be a "young devil" and iodine an "old man with a past." Allotropy is explained as a sort of "Dr. Jekyll and Mr. Hyde" state of matter. The stories of the elements and their compounds are enlivened by up-to-date examples of chemical application in the arts. In this way the author brings in the Cottrell process, permutit, fixation of nitrogen, and the simple metallurgy and uses of the metals. War time is reflected in the mention of war uses for chemicals, notably explosives. All the romantic interest attaching to the chemistry of carbon compounds is brought before the reader in as much detail as the scope of the book will permit. The wide distribution of the book will make for an enlightened public intelligence on the great chemical industry which is bound to grow in importance in this country.

LABORATORY GUIDE OF INDUSTRIAL CHEMISTRY. By *Allen Rogers.* 212 pages, illustrated. Price, $2.00 New York: D. Van Nostrand Co.

A laboratory manual of Industrial Chemistry prefaced by a brief description of the more common forms of industrial chemical apparatus. Then follows a series of experiments in inorganic preparations, the raw materials being used in about one kilo lots. Typical preparations described are magnesium sulphate, potassium permanganate, sodium thiosulphate, sulphur monochloride, etc. A chapter is devoted to organic preparations corresponding to those usually given in a beginning university course in this subject.

The main part of the manual is devoted to well-chosen experiments in the dyeing of textile fibers, pigments and lakes, driers, varnishes, paints and stains, soaps and allied products, leather manufacture and wood fiber and paper. In each case the detailed experiments are preceded by a concise statement of the main principles involved. The experiments aer representative and reflect factory operations, and should be of great value to the student, especially when they are carried out under the foremanship system as at Pratt Institute, where "groups of students are assigned to work in model plants, one member of each group acting as foreman. The foreman is held responsible for the quality as well as the quantity of the output of his plant, must see that the machinery is left in perfect condition, and that the factory is kept clean." Few schools could carry this method out, which ought to give good results, but the text should be a workable one, even with less equipment than the foreman method involves.

* * *

A PRACTICE BOOK IN ELEMENTARY METALLURGY. By *E. E. Thum, E. M.* Octavo (15 x 23 cm.), 321 pages, 57 illustrations. Price, $2.75. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd.

The author was assistant professor of metallurgy at the University of Cincinnati, and prepared this book for the use of his students, who, according to the system there in vogue, come to the university in alternate two-week periods, spending the other periods in shops or works. The limited time allowed for lectures gave little opportunity for discussing with the students the principles underlying the experiments, so it was decided to write a laboratory manual for them and print the explanations therein. The subjects covered by the experiments are well chosen, and students carrying them through and studying the text cannot fail to learn some good metallurgy. On the other hand, the details are so closely connected with the local conditions and limitations under which the author labored that the general usefulness of the book is greatly impaired thereby. It may be a very useful handbook at the University of Cincinnati, and it might be of very little use in some other institutions differently situated, with different equipment, and with students working on a different plan of instruction. It is, however, full of good suggestions for anyone planning metallurgical laboratory work.

The Chemical Market in the United States in 1917

Coal Tar Products

During the past year additional strides were made in the production of coal tars and intermediates; in fact, this branch of the chemical industry continued to hold out the most glowing prospects in the way of a quick return on the money invested, which, of course, is always the primary consideration in the establishment of a new industry, inasmuch as it is then possible to secure sufficient financial backing to carry forward the perfection and completion of experiments with the proper degree of assurance. While the years 1915 and 1916 saw considerable in the way of improvements, not only in production, but also in the quality of the products, the year just passed has eclipsed the records of these years to such an extent that they seem to be mere memories, as we review the happenings' in 1917. At the close of 1916 practically all the intermediates were being produced, with the exception of a few, which were more difficult to produce and bring to a state of perfection. But during 1917 ideas were developed in a slow, painstaking manner and concentration was more generally adhered to in an endeavor to overcome the temerity of consumers of American products, who had been disappointed when they found that these products could not be used to the same advantage as the foreign products to which they had been accustomed. With renewed application some of the larger producers succeeded in overcoming the prejudice thus engendered by the production and perfection of high-grade products, with the result that as the year ends there is practically nothing that Germany produced that we have not been able to master.

For a time the pioneers in the field of production in specialties waxed fat on the new industry. But the way of the world was not different in this case than others, and as soon as it became apparent that this new field offered such wonderful opportunities, many new companies entered into the line, with the result that at the end of the year only a few of these concerns were able to weather the sea of competition, with its slashes in prices and general undermining of the industry, and the year ends with only the stronger factors surviving and prices on a lower parity. The tendency in general is rather to build up a regular trade by the pro-

duction of a standard product at a good though not unreasonably large profit. With this object in view, many firms have established for themselves a name that is synonymous with quality and their success is encouraging.

As the year draws to a close several producers of the intermediates have curtailed and some have closed down owing to governmental seizure of toluol and phenol, except when used in the fulfillment of requirements for the government. But it is the general impression that the authorities at Washington will shortly arrange matters so that the industry will not be destroyed. Release of material to consumers is expected shortly, through the medium of committees.

The industry on the whole has not been affected by the entry of this country into the war.

Coal Tar Crudes

Production figures of benzol are not available, but greater quantities were produced this year than last year, and authorities believe that the total will be several million gallons over last year's estimated total of 30,000,000 gal. There were 70 concerns with benzol recovery apparatus as against 61 in 1916. While the output in 1916 was fairly well absorbed, the quantities produced in 1917 were greatly in excess of the demand, as there was considerable falling off in export requirements, with the result that prices have been tumbling for the past few months and apparently have not yet reached the bottom. Benzol on spot can be done now at 36c. to 40c., according to quantity and buyer and seller, as against 75c. to 60c. in 1916, and 77c. to 80c. in 1915. Contract business over 1918 is being done at 36c. to 42c. for the pure material. The 90 per cent grade is not produced in such great quantities and a higher price obtains for this material than for the pure, but some rubber manufacturers apparently prefer this grade.

Toluol.—During the year prices did not vary greatly from those prevailing at the close of 1916. For the most part $1.50 to $2.00 covered the range. However, in November the government requisitioned the entire production for use in the manufacturing of explosives, and such quantities as were in dealers' hands have since sold at fancy figures. As high as $3.50 a gallon has been paid for small quantities. Producers of intermediates to be used as dye bases, or in other necessities, have been favored with releases of moderate amounts, but they are for the most part operating on a hand-to-mouth basis. It is probable, however, that a committee will be appointed to handle in a business-like way the matter of releases. The 1917 production was much greater than the 8,000,000 gal. produced in 1916, but accurate production figures are not available.

Xylol.—The production was greater during the past year, with large surplus quantities backing up on the market, the price for the different grades ranging from 30c. to 50c., according to quality and quantity, as against 50c. to $1.20 last year.

Naphthalene.—The production has been materially augmented but with only comparatively small quantities being imported from England because of heavy duties, domestic manufacturers had a better opportunity to dictate prices, but the variation in price during the whole year was not great. From 8c. to 9½c. covers the range, and at the close of the year sales were consummated as high as 9¾c. for prime white flakes. Off color material sold at slightly less. The ball material was selling at 10c. to 11c. The total production in the United States was estimated at approximately 25,000 tons, as against 12,500 tons in 1916.

Phenol.—Phenol has probably been the feature of the list with prices fluctuating from day to day, and at times from hour to hour. There has been a steady demand, both for export and domestic consumption, in the making of intermediates for dyes and explosives. The production has materially increased and at times this has had more or less bearing upon prices. At the beginning of the year prices held at 53c. to 55c. and from time to time prices varied over a wide range, until the low level of 40c. was reached. Eventually, however, as surplus quantities were absorbed, a firmer undertone prevailed, until at the end of the year prices had gradually climbed back to their former position and 50c. to 53c. was the prevailing figure. About Dec. 15, however, the government began commandeering this product for use in the manufacture of explosives, and it was understood that producers were to receive 38c. a pound. In general offerings to the regular trade were restricted until such time as governmental requirements were filled. The production during 1917 was estimated at 25,000 tons as against 12,500 tons in 1916.

Intermediates

Great strides were made in the production of the intermediates and some of the problems that had not been solved in 1916 were brought to a successful conclusion in 1917, and practically every item of importance on the list was being produced. Aniline oil, following in sympathy with benzol, was produced on a lavish scale, and for a time the large quantities were being offered at a premium, but the producers finally got matters in hand to a certain extent, and from 25½c. to 26c. was the prevailing price, figuring in transactions of moment. Producers, while making large contracts over next year at these figures, were endeavoring to secure 28c., with a limited degree of success. The quality of the oil produced continued high and met with favor in the trade. While production was considerably greater than in 1916 authorities were unable to give exact figures.

Aniline Salts.—While the production followed closely that of aniline oil, the salts were more readily absorbed and prices did not reach as low levels as the former. Several producers dropped out, the field therefore being easier to check up. At the close of the year second hands were offering at 28c. and 29c., with producers asking 32c. to 34c.

Nitro Benzol.—The production was heavy for a time, and the market was flooded with supplies, but several producers discontinued this line, and the position was slightly improved, although there is still a plenitude of supplies. At present the market is quiet, with 17c. to 19c. quoted, and contracts involving large quantities have been made as low as 16c.

Toluidine.—This item was being produced by about a half dozen concerns during a part of the year; at the close there were but two factors in the field who were producing both, the *ortho* and *para*. The toluol situation has not yet affected same, and the *para* grade was bringing $2.00 to $2.25, with the *ortho* at 85c. to 90c.

Picric Acid.—The production narrowed down to a very few producers, who, for the most part, were catering almost exclusively to the Government, and but very little was procurable in the open market.

Tri Nitro Toluol.—Governmental needs have resulted in the elimination from the open market of this product.

Para Nitro Toluol.—This product was rather extensively produced, being in goodly demand with dye producers. However, the quality was not always up to specifications, with the result that those who had not been able to produce a quality product rapidly dropped out, until at present there are only two factors in the field, with $1.50 to $1.60 as the prevailing price.

Ortho Nitro Toluol.—The conditions were much the same as in para nitro toluol, with only a few factors holding sway, with 75c. quoted as the inside figure.

Metanitroparatoluidine.—This material was in goodly demand, with production restricted to a few quarters and material scarce, with $5.50 quoted.

Paranitraniline.—While during the early part of the year many producers were behind in the fulfillment of contracts, the increased demand from dye producers, however, was instrumental in increasing the production, and for the past few months it has been freely offered at $1.10 to $1.15 as against $1.60 to $1.70 last year.

Alpha Naphthylamine.—This product is closely identified with dye production, and has been produced in large quantities. Prices have declined as a result, and it was possible to do 58c. to 65c. as against $1.25 a year ago.

Dimethyl Aniline.—Of considerable importance in the production of some dyes, large quantities were manufactured and prices were not subject to much change; from 55c. to 60c. prevailed.

Diphenyl Amine.—Has been in fair demand with the producer of dyes, but of late munitions requirements have been heavy and there is but little procurable in the open market. It sold at times from 85c. to $1.00.

Para Phenylene Diamine.—The production for the most part was confined to one quarter, with a good demand. Prices have been well maintained at $3.50 to $4.00.

Metaphenylene Diamine.—Only two or three producers are in this field, and there is a goodly demand, with a scarcity at present, and $1.75 to $2.00 is quoted.

Para Nitro Phenol.—This material is used extensively in developing by photographers. Goodly quantities were produced, with the demand fair and prices at $1.50 for the powdered crude material and $2.00 for the needle crystals.

Ortho Nitro Phenol.—Was produced in goodly quantities by several concerns for a time, but most of these dropped out. The demand from fur dyers is heavy, with supplies light and prices at $1.40 to $1.50.

Beta Naphthol.—An abundance of this material has been produced; so great were the quantities on the market that prices were forced down from $2.00 to 65c. for the technical grade and from $2.75 to 85c. for the sublimed material.

Para Amido Phenol.—The production has been heavy during the past few months, and competition is keen, but the cost of raw materials tends to keep prices at a fairly high level and from $4 to $5.50 is quoted for both the hydrochloride and base. Ordinarily there is a difference in price between the two. One producer has recently placed upon the market a needle crystal which is expected to attract some attention.

H Acid.—During the year there were as many as 8 to 10 engaged in the production of this acid with a total output estimated at from 125 to 150 tons monthly, but as the demand eased off, several dropped out and at present there are about six who are producing quantities of moment. Prices vary with $2.15 as the inside figure for the paste, from $3.00 to $3.50 for the 100 per cent and $2.50 for 97 per cent.

Gamma Acid was produced in a limited way by one or two concerns, but inquiries in the market for large quantities of spot material failed to locate same, and orders for fairly large quantities were unfilled.

Neville & Winthers Acid is being produced in goodly quantities, but the demand of late has fallen off somewhat, and $2.00 is quoted for 100 per cent material in ton lots.

Benzoate of Soda.—This item has had a very interesting career since the commencement of the war in 1914. At that time we were almost wholly dependent upon Europe for our supplies. In August, 1914, it was selling at 23½c. a pound. Prices increased by leaps and bounds until in December, 1916, the soda sold for $8.50 a pound, and the acid at $10.00 to $12.00 a pound. A number of large producers entered the field, a price-cutting campaign was launched, and the weaker factions were eliminated. During the past few months inability to secure toluol has curtailed production and prices are once more in the ascendant with $3.00 to $3.50 as the prevailing prices respectively for the soda and the acid.

Salicylates were produced on rather a heavy scale, but prices are somewhat higher than they were a year ago, although the demand at present is not pressing for the sodium which is selling at $1.30 to $1.35. Salicylic acid, however, has met with a goodly demand, and there are large quantities being produced, which are selling at $1.10 to $1.30 for spot or prompt material and 85c. to $1.00 on contract for the U. S. P. grade. The technical grade is not in great demand, with price quotations at 75c. to $1.00 for spot material.

Aniline Dyes

Great progress was made in finished dye production in 1917, and the relations between producer and consumer are very satisfactory. The improvement in quality and variety has been very pronounced. In 1915 the total domestic production of aniline colors amounted to $2,470,096. The exports for the fiscal year ending June 30, 1917, were valued at $11,710,887 as against $5,102,002 for the same period in 1916. These figures include both aniline and natural dyes, however. Anilines are more than 50 per cent of the totals.

During July, August and September British India purchased dyes from us to the value of $84,967, Canada $161,581, Spain bought $105,505 worth of dyestuffs during this time and France bought to the extent of $86,379, Japan $80,073, Mexico purchased to the value of $75,353 and Italy $67,484. At the present time American color producers are well armed to compete with German dyestuff manufacturers in regard to most colors. Of late the markets on benzol, phenol and toluol have been tight, affecting domestic color producers. A number of small firms formerly making malachite green crystals have gone out of business for the want of toluol. It is noted that many firms previously engaged in other lines of business have entered the dyestuff industry and are now listed among American color producers. A cotton concern in the South, for years engaged in the cotton business, is now producing sulphur colors, and an ink firm in California who, for many years, was solely engaged in the manufacture of various inks, has entered the dye business and is now producing a lithol red. Another ink firm in Cincinnati has invested large sums of money in a plant to manufacture colors, and is now producing a metanil yellow. This same firm is making paranitraniline, from which para red is produced. To-day we find large and small manufacturers of colors from all over the United States busily engaged in experimental work. The fuchsine produced in this country rivals the German standard "Diamond" brand goods in both strength and shade. Primuline is being made here in fairly large quantities. Exporting to South China and Japan is demanding the attention of American color manufacturers as well as exporters. Pre-war figures show that Hong Kong used annually around $1,000,000 worth of dyes. Shanghai is another dye center. This section has been accustomed to using natural dyes and vegetable indigo, and the uses of aniline colors are not thoroughly understood as yet. According to reports, Germany has established centers in the leading dye districts of Japan and China for the instruction of the local dyers. It is generally thought that in order for the United States to establish a firm trade in these countries the business will have to be worked out along these lines. Some Japanese dyes are offered in the United States, however. They do not meet with the approval of important mills. Seemingly high standards have not been established in Japan as yet. The principal color made in Japan is yellow. The South American trade calls for the cheaper grades of anilines. The Spanish export trade is demanding considerable attention and orders for $150,000 worth of dyestuffs at one time are not infrequent. Spain buys some of the more difficult colors, including metanil yellow, patent blue, azo yellow, malachite green, fuchsine. All concerned are looking forward to a prosperous year in 1918, and it is expected that many of the complicated German colors will be produced during this period. At this writing there are 136 actual producers of anilines in America. The State of New Jersey leads with 47 color manufacturing plants, New York has 30 representative plants, Massachusetts is third in line with 11 plants, the Keystone State is represented by 7 plants. Other States are named in order of their importance as follows: Connecticut, Michigan, Ohio, Rhode Island, Illinois, North Carolina, Missouri, Maryland, Minnesota, Washington, Florida.

Heavy Chemicals

The production of practically every chemical under this classification during the past year was by far the heaviest in the history of the industry, and while there was a great element of speculation still noted in a number of the items, the market presented many aspects of stability. In certain items prices receded to levels that prevailed prior to the European war. At the moment of writing the entry of the United States into the conflict has had surprisingly little effect on conditions generally. However, it must be realized that the organization of the innumerable purchasing divisions in the national capital has taken a great deal of time and it was only toward the close of the year that these official organizations began to show their authority. There seems to be but little doubt current that a large number of the industries will eventually come under direct governmental control with prices fixed.

Potassium Salts.—A comparatively tame year was again reported in these products. German muriate of potash sold throughout the twelve months at about the unchanged level of $350. Moderately large quantities of Japanese muriate reached this market from time to time, and as is usual with a new product, consumers were inclined to discount

its value. The first shipments did contain a rather heavy sulphate content, and it is now stated that this and other impurities have generally been removed, so much so that the Japanese product generally commands a price close to that secured for the German material. The production from domestic sources continued in a larger way. As heretofore the Nebraska lakes furnished the bulk of the production, but it is not thought likely that the present production in this country from lake brines, cement and other sources totals as yet 15 per cent of the normal consumption before the war.

Ammonium Salts.—During the year the usual development of the trade that possibly stands out most is that fact that there were unusually large export shipments of sulphate of ammonia to England—heretofore the principal producer—and to countries that England heretofore shipped exclusively. As a matter of fact, sulphate of ammonia passed about out of the category of a domestic fertilizer material. On Oct. 1 an embargo on exports stopped this trade, but there was such little material available that the market was not noticeably affected; as a matter of fact, the high price of 7.30 double bags f.a.s. was quoted toward the close. The quotation at the beginning of the year was 4 50. *Ammonium nitrate* was a product that brought with it many disappointments toward the close of the year. After an unusually heavy export inquiry the demand suddenly ceased and prices dropped off so that to-day there is much material on the market that cannot be moved at even 19c. At times during the year the price rose to 21c. The manufacturer of this explosive has been up against a most serious problem in the matter of raw material. Upon the entering of the United States into the war the demand for anhydrous ammonia for refrigeration purposes for the enormous foodstuff supplies for the armies both at home and abroad brought the attention of the authorities to this situation. Considerable speculation had already been rife as a consequence of the heavy demand from the Allies. Toward the close of the year the government has consulted with the leading producers, and it is generally thought that an understanding has been reached whereby the production of ammonia will be principally of the liquor to the exclusion of sulphate and aqua ammonia. The nitrate manufacturers have been assured of their supplies. The government's price is 14c. *Muriate of Ammonia* (sal ammoniac) has been in increased demand and from a normal price of 5⅞c. for the gray material it is difficult to purchase the product now at 15c.

Nitrate of Soda.—The imports for the fiscal year ending June totaled the record amount of 1,261,658 tons, valued at $44,231,240. This compares with 1,071,728 tons valued at $32,129,397 during the corresponding period of 1916. Notwithstanding the enormous tonnage brought into this country prices reached new record levels, and some lots at one time changed hands at 5.25, although 5.10 was about the high level for important business. Toward the end of the year, however, there was a large amount of resale material offered, and seemingly the tonnage purchased early in the year had not been absorbed. These sales forced the market down to approximately 4.60. Of the manufactured *sodium salts* the sulphites came in for much attention, particularly *sodium sulphite* for moving picture developing. *Chlorate of soda* sold at 20c. for contract, but the production held well and generally firms not under contract at this figure had to purchase in the market at a higher level. *Acetate of soda* was another item under this classification that attracted much buying attention. At the close of the year the market was absolutely bare, and a nominal quotation of 17½ to 18c. prevailed, with sellers not inclined to quote for next year. *Nitrite of soda*, as a result of several new manufacturing sources entering the field, including an air nitrogen concern on the Coast and one of the largest explosives manufacturers, has receded from its high level of 58c. reached at one time during the year to the present level of 30c. at which contracts for 1918 are being offered. Owing to the restricted production of *silicate of soda* the product was generally at a premium throughout the twelve months. The product is one that has attracted but little additional capital, and so far the production, particularly of the 60 deg. material, has not increased sufficiently to take care of the consumption. *Sodium sulphide*, which is a by-product with the barium salts industry, has been scarce, and to-day commands a price about double that prior to the war.

Sulphuric Acid.—The feature of this all-important branch of the chemical industry during the past year has been the great scarcity of Spanish pyrites as a result of the submarine scare and the abnormally high freight rates, with the result that a large number of the acid plants heretofore burning pyrites were as a result of this situation compelled to install apparatus for the burning of brimstone. This, of course, meant radical change in the operation of the plant, requiring in many instances a new study of manufacturing problems. However, the crisis has been well met and to-day the production of sulphuric acid is by far the heaviest that has ever been recorded in the history of the American chemical industry. The entry of the American government into the war naturally would eventually make its influence felt in the chemical industry, and sulphuric acid was the product that was to feel this influence first. Until we were actually at war the markets presented rather weak aspect. Acid was to be obtained at prices representing not a great enhancement over those before the European conflict. At the moment of writing the situation has become so uncertain that many factors are predicting $80 acid by the spring and $200 oleum. This, of course, refers to acid for the outside market. It is reported, but not so far definitely confirmed, that for government account manufacturers will be compelled to furnish 66° deg. brimstone acid at $28 works, with a probability that the brimstone will be furnished by the government at a fixed price. It is understood that already some of the Southern fertilizer works have been furnished brimstone for acid manufacture at $22.00. Acid for the ordinary consumer at the close of the year was generally held at $38.00 to $40.00 for the 66-deg. brimstone, buyers' tanks, as sellers' tanks were not generally available. The government will undoubtedly sooner or later assume control of the industry, and it is reported that already consumers have been classified in four divisions, and will receive acid according to their relative classification.

Nitric Acid.—At the time we write the nitric situation has not shown particularly noticeable results of the country's entry into the war. Undoubtedly it will but with the nitrate of soda market easier and consumers not very much interested sales are not urgent. At one time during the year prices ranged from 14 to 15c. per unit, but toward the end of December 42-deg. material was available from 8c. to 8½c. per pound from various manufacturers.

Muriatic Acid.—The year was a tame one for this product. The movement was generally about what might be expected in normal times, but toward the close of the year the material was rather scarce and prices gave promise of reaching a higher level. However, values were not subject to much fluctuation during the twelve months. The scarcity of carboys tended to restrict the movement somewhat.

Acetic Acid.—The first half of the year witnessed an extremely active and heavy demand for practically all grades of acetic acid, particularly glacial. The last half of the year was featured by an extremely quiet and dull market, with the product mostly offered by second hands and probably resale material. Glacial acid sold well above the 30c. level throughout the interval, reached 36c. or 37c., and at the close was available at 33c. to 34c. Fifty-six per cent material closed at 5½c. from second hands, and a lot of 30 long tons of 80 per cent material changed hands toward the end of December at 11½c. As there is now an embargo on exports of acetic acid and acetates and the government has taken over the wood distillation industry, interesting developments are to occur.

Lactic Acid.—An increased production and rather quiet consuming demand throughout the year brought with it but little change for this commodity. The year closed a fraction above the prices ending 1916, with market conditions quiet.

Phosphoric Acid.—The production has seemingly set pace with the demand, and at the close of the year the 47-48 per cent acid was quoted at 7½c. as against practically double this price at the close of 1916.

Oxalic Acid.—While several new productions were inaugurated or planned, as yet none of them have seriously affected conditions here and the original American manufacturers continue to dominate the field. The price now current is 45 to 46c. as against 43 to 45c. at the close of

1916. Dutch oxalic acid has practically disappeared from the market as a result of freight difficulties.

Cyanides.—During 1916 the soda reached the high level of $1.75 to $1.80. Since then there has been a gradual recession and to-day second hands are offering the material at prices ranging from 44c. to 46c. as to point of shipment. The new plant of the only American producer in Vermont will increase the output here, and this of course does not tend to strengthen the market. The producers as heretofore sell only to the regular trade on contract and trading in outside lots is perforce in second hands.

Bichromates.—The production of both soda and potash continues well under the control of the leading producer, and so far there has not been a production sufficiently important to interfere with the operations of this concern which establishes the market, and prices generally follow their views. The 1917 contract price, it will be recalled, was 24c., but the outside market was generally below this during the year, although on some occasions it was slightly higher. The 1917 price is 16½c., but owing to under freight conditions from New Caledonia and the possibility of the government commandeering the chrome supplies, contracts are reported to contain a clause permitting the producer to advance prices under certain conditions incidental to these conditions. The year closes with second hands quoting jobbing lots at 17c. There are about eight plants with equipment for bichromate of soda or its equivalent production, but the production is principally confined to three producers. A new small producer plans a production for 1918. *Bichromate of potash* had a very uninteresting year. One of the three producers ceased manufacturing.

Copper Sulphate.—The export of this product is of course the mainstay of the trade and up to the end of September it revealed an increase over 1916, but toward the end of the year there was a great amount of difficulty noted in exporting and prices receded to the lowest level that prevailed for a long time. At the beginning of the year the large 99 per cent crystals were selling at 13c. to 14c., but in December, 1917, second hands were quoting Nichols brand 99 per cent large crystals as low as 8⅞ per cent, although the producers' price was 9½c. There are some eight or ten firms now equipped to manufacture this product, but as heretofore the production is principally in the hands of the Nichols Copper Company and the American Smelting and Refining Company.

Caustic Soda.—A record of events in this market during the year would be merely the tabulation of price changes practically hourly. Such speculative activity has never been witnessed off Wall Street. The production was sold undoubtedly thirty or forty times over. Bills of lading have come to light with as many as twenty-four indorsements, and in some instances a purchaser of a car of caustic found his own indorsement on the bill two or three times. The extent of this trade may be readily grasped when it is considered that there are probably a hundred firms in the various cities working on a brokerage basis and dealing exclusively in caustic soda and soda ash. At the opening of the year the spot price for 76 per cent caustic soda in New York was 4½c. From this level there was a steady climb until in September a level of 10c. was reached. Effective Oct. 1, the government placed the product on the conservation list with the result that in one day there was a drop of 2c. The export trade has grown beyond the dreams of the most optimistic member of the industry. There are no statistics available yet concerning the total of this trade, but from the port of New York alone the shipments totaled four, five and six thousand tons monthly. The works have generally been sold out during the year. The market has been exclusively in the hands of traders. When the drop occurred on Oct. 1 the market continued to weaken until at the close of the year spot cars were selling at 6¾c., New York, with contracts over 1918 from reliable dealers generally held at 6½c. works or New York. The production at the moment is in the hands of some twenty-six or twenty-eight firms. Just how large the output is no one seems to know, but it is estimated to be from 750,000 to 1,000,000 tons.

Soda Ash.—The market has been more or less a repetition of caustic soda but prices were not subject to such wild flurries. There was much speculation, but the product was not so closely controlled. The year opened with bags quoted at 2.95c., and from this there was a steady but slow climb to the high point of 4.25, which was reached late in August. In October the market eased off somewhat in sympathy with caustic soda, and remained quiet until Dec. 1, when this product was also placed on the conservation list and exports prohibited. Exports have been reaching the unusual large amounts of five, six and seven thousand tons monthly from New York alone. As was the case with caustic soda, the market was in the hands of traders during the year and the works were not generally quoting to this class of trade. The year closed with spot bags quoted at 2.75 to 2.80, and contracts over 1918 at 2.95 to 3c. The production is estimated to be from 800,000 to 1,000,000 tons, and there are possibly thirty or forty producers.

Bleaching Powder.—The year has been a disappointing one for bleach producers. The installation of chlorine cells by the large consumers resulted in a neglected market and at one time during the year there were sales as low as 50c. per hundred pounds for 35-37 per cent material from warehouse New York. The production is placed at 150,000 tons. At the close of the year there was a firmer tone prevailing, and it was difficult to shade 2c. for fresh bleach and for 1918 shipments producers were quoting from 2½c. to 2¼c.

Chlorate of Potash.—It is generally presumed that the bulk of the contract requirements for 1917 were placed at figures ranging from 70c. to 75c. These buyers covered to their regret for the production seems to have exceeded the demand somewhat as the market from second hands never reached the contract price. There has been a gradual recession of values until toward the end of the year resales on these contracts were occurring as low as 35c. The 1918 price has not been announced as we write, but a statement has been made that 40c. is too high and the probabilities are that the figure will be below this level somewhat.

Current Market Reports

The Iron and Steel Market

Iron and steel prices as set by the War Industries Board and the American Iron and Steel Institute are likely to stand for some time. Conferences between the War Industries Board and the Federal Trade Commission and the iron and steel makers held during December have not indicated any strong desire upon the part of the Washington authorities to seek a downward revision of prices at this time, while the manufacturers have no hope of securing an upward revision. The Federal Trade Commission will probably push the Pomerene iron and steel price-fixing bill in Congress, with a proviso for the abrogation or suspension of some contracts. The trade commission has been rather puzzled at the wide diversity of costs shown in reports it has been receiving during the past six months, some being so high that a reduction in the set prices might operate to decrease production, and its only hope of paving the way for reductions appears to be in removing the effect of some high-priced contracts for raw materials. The Pomerene bill could hardly be passed before some time in February, and as it would merely empower the President to act it would be some time before real action would be taken, if indeed any at all were taken.

Commercial Demand Very Light

The ordinary commercial demand for iron and steel has become extremely light, while during the second half of December practically none of the demand that may exist has been expressed. Buyers have been busy with year-end adjustments, particularly complicated this year, and have had no interest in the market.

Buying by the government has continued heavy, if indeed it has not increased. It is estimated that about 1,200,000 tons of the 1,500,000 tons of shell steel required for delivery by the middle of June has now been placed. A very considerable tonnage has already been produced, as shown by the relatively free offerings of discard steel in the open market. This material will be rolled into billets down to 1½ in., and is offered at about $2.50 below the set prices for soft steel billets. There is no precise information as to other steel re-

quirements of the government, but orders are being placed right along.

A comprehensive program involving cars and locomotives has been worked out at Washington against any decision that may be reached as to what is to be done with the railroads. This is a measure of preparedness, as, whether purchases of rolling stock to increase the capacity of the railroads are to be financed by the railroads or by the government, it will be necessary for the government's authority to be used to secure the earliest delivery of the raw materials for the rolling stock and its earliest manufacture.

Traffic Conditions

Traffic conditions as affecting the iron and steel industry have been worse in the second half of December than in the first half. In the Central West generally there has been a shortage of both coke and coal deliveries, worst along the lake front, with the Youngstown district coming next and the immediate Pittsburgh district faring relatively well, though suffering considerably. Production in the South has been fully up to normal, while conditions have been fair in the East. December production as a whole has been 5 to 10 per cent under the average of the first eleven months of the year, in which period there was production at 90 to 95 per cent of theoretical capacity.

The railroads were greatly affected by the cold wave of Dec. 8, which brought an average of zero weather to the Central West. Although the coldest weather lasted only about three days the railroads have not recovered. The difficulty is not so much congestion, as the operation of the pool of Eastern railroads had relieved conditions materially in that respect, as it is a shortage of motive power, evidently resulting from many locomotives having been incapacitated during the cold snap.

It is a small thing apparently that stands in the way of full production in the iron and steel industry, the movement of a little more coke and a little more coal, and it seems strange that the railroads have been unable to compass the extra movement. On the other hand, it is quite possible that if there were the extra production it would be impossible to move the additional finished product or serve the manufacturing consumers who would receive it. While there is a great deal of talk it is not made clear that the war activities or the ordinary peace activities of the people are really suffering from a shortage of steel.

Pig Iron

The demand for pig iron from iron foundries is light. While deliveries have been curtailed through irregular operation of merchant furnaces, the consumption of the iron foundries in general has undergone a great decrease. The steel works are all more or less short of pig iron and would buy in the open market, but there are practically no offerings. If the furnaces were in position to sell they would sell only at the set prices, based on $33 at furnace. Some Alabama basic iron has been sold in the Pittsburgh district at this furnace price, involving a freight of $4.55, when if the iron had been bought in the valleys the freight would have been only 95 cents.

Finished Steel

With total output curtailed steel is being put into the forms most needed. Shell steel production is practically up to requirements, being chiefly a blooming-mill proposition. The plate mills are almost fully supplied, slabbing mills being operated full while all the blooming-mill slabs possible are being made. Sheet bars are being fully supplied to tin mills, which are operating at about 95 per cent, while supplies to sheet mills are correspondingly light, entailing an average operation of 50 to 60 per cent by the sheet mills. Production of welded-steel tubular goods is off somewhat, but shipments of oil-country goods in particular are well maintained. Wire production is somewhat curtailed.

Non-Ferrous Metal Market

Wednesday, Dec. 26.—The copper situation is somewhat easier, and signs are evident of larger supplies being available owing to reduced consumption and foreign shipments. Straits tin is very scarce. Lead is unchanged. Spelter has been dull and a little weaker.

Copper.—A meeting was held in Washington on Dec. 14 between the War Industries Board and representatives of the copper producers, to discuss the copper question for 1918 as regards requirements and prices. The producers, especially some of the smaller ones, said that present copper prices were not high enough to stimulate maximum production. Assurances were given that the producers could meet the country's needs. Lake and electrolytic remain at 23.50 cents with 24.67½ as the jobbers' price.

Tin.—Tin has been very scarce and at present there is no Straits tin on the market. Arrivals to Dec. 19 were only 1115 tons, and if any were for sale it probably would bring somewhere between 85 and 90 cents. The production of American electrolytic tin is said to be relieving the situation somewhat. Fortunately the demand does not appear to be extra heavy. All grades are very scarce.

Lead.—After a long conference on Dec. 17 between representatives of the principal lead producers of the country and the War Industries Board of the Council of National Defense, it was announced that no regulatory action affecting the industry would be advocated at this time. The question of fixing prices and providing for distribution of the lead output under Government control was discussed at length, and it is understood that the producers promised co-operation on the present basis, which was satisfactory to the board. The Trust price of 6.25 New York remains unchanged. Outsiders are asking 6.50 to 6.75.

Spelter.—This market has been dull, with prompt prime Western quoted at around 7.50 St. Louis, and brass special at 8.00 St. Louis.

Antimony.—There is no change in antimony. Prices remain at 15 cents for prompt delivery, with needle antimony at 9¼ to 9½. Antimony ore is quoted at $1.75.

Tungsten.—The market has been firm in New York. Charles Hardy says that "on account of a very large foreign inquiry coming in at the same time as one of our largest users at home appeared into the market, the tungsten market has been exceedingly firm during the past week and most good grade ore in New York found ready buyers. even material on steamers shortly due was readily absorbed by the market. The tungsten price remained very steady at a slight advance and $24.50 was paid for high-grade wolframite, with prices ranging lower for off-grade ore. Such scheelite as was offered was readily sold at $26 per unit."

Molybdenum.—Demand for molybdenite is reported good and prices range from $2.25 to $2.30.

Chrome.—Very little high-grade chrome ore is offered, and the demand is good. The price remains at 90c. per unit, at California.

Quicksilver.—Very little spot material is available, as arrivals are very slow. California virgin is quoted at $115, but higher prices have probably been paid.

Other Metals

Aluminium, lb.	36–38
Bismuth, lb.	3.50
Cadmium, lb.	1.50
Nickel, electrolytic, lb.	.55
Silver, oz.	.86⅝
Platinum, oz.	105.00
Palladium, oz.	130.00

Chemical Market

Coal Tar Products.—Interest continues to center in this branch of the industry, although there has not been as much activity of late as heretofore. The government has added phenol to the conservation list, and it is unlikely that any material quantity will be released for ordinary commercial purposes. With both this product and toluol practically off the market the result is at least a temporary lull in trading. The situation in general is interesting and holds forth promise of future developments that may cause further decrease in supplies of essentials.

Benzol.—Continues weak. Large surplus stocks continue available at low figures and further concessions are believed possible.

Toluol.—The situation affecting this product is unchanged. There is practically none to be secured in the open market, the entire supply being in the hands of the government.

Naphthalene is firm and the market is quite bare of supplies, but a replenishment is expected shortly.

Phenol.—The government has taken over practically the whole production, and but little is available for ordinary trade requirements.

Benzoate of Soda is scarce and firm, with a fair demand, but only light stocks are held.

Monochlorbenzol.—The production is heavy and large surplus stocks are procurable at favorable prices.

Paranitraniline is being produced in large quantities, but there has been a better demand of late.

Metanitraniline continues to be offered in a liberal way, with the demand light.

Aniline Salt is slightly firmer, with second hands pretty well cleaned out and producers in command of the situation.

Aniline Oil spot stock continues to be offered in a liberal way at fair prices, but an advance is expected on business over next year.

Para Toluidine.—The market is firm, with production restricted on account of the toluol situation.

Ortho Toluidine.—While the demand is not heavy, production is somewhat restricted and the position is firm.

Tolidin continues to be in fair supply, but concessions are impossible because of the light supply of toluol.

Antracene is in goodly demand, but there is a scarcity. A recent large sale appears to have cleaned out available supplies and higher prices are obtained.

Para Nitro Phenol is in goodly demand, with a fair production, and prices are unchanged.

Ortho Nitro Phenol.—At present the demand is greater than the supply, but new producers are entering the field. Prices are unchanged.

Salicylic Acid has been sold in large quantities of late, with prices unchanged because of large production.

Nitro Benzol has figured in goodly sales of late, but the production is heavy and prices are low.

Beta Naphthol has been in better demand of late, but large surplus quantities tend to keep prices down.

HEAVY CHEMICALS.—As is usual in December, there is a quiet and generally a weak market prevailing. This December has been no exception to this rule, and trading during the past two weeks has been of a very minor character, with prices generally inclined downward. Oddly a few items that have been quiet practically throughout the year end the year with a strong feeling prevailing.

Caustic Soda.—A much easier market has prevailed since our last report, and selling pressure has resulted in a spot price of about 6¾c. ex-store. This new figure is probably accounted for by the fact that some second hands in fear of a lower 1918 market have liquidated their holdings. For 1918 deliveries most of the reliable factors quote 6.50 for two or three cars monthly from the works. Other traders are quoting lower but the usual uncertainty regarding deliveries makes a buyer hesitate somewhat before closing with these firms.

Soda Ash.—Real soda ash is not easily obtained for nearby positions. This condition of affairs is readily discovered if a buyer attempts to cover. The demand for spot and nearby, however, is fortunately for buyers not particularly heavy, and the market remains more or less inactive. Over 1918 there are sellers quoting 2.95 to 3c. for bags. Barrels are generally held at 3.15 works, but one contract from New York is available at a lower figure.

Copper Sulphate.—The market has been subject to a sharp drop. Nichols brand from second hands has been offered as low as 8⅞c., although the producers still quote 9¼c. to 9½c. The lack of export trading is the cause of the present slump.

Cyanides.—There has been no change of special moment. Offers from second hands are reported from various points at prices ranging from 44c. to 45c. for the sodium. The so-called potassium has seemingly disappeared from the market. The new plant in Vermont will result in an increased 1918 output.

Bleaching Powder.—After practically twelve months of inactivity there are now more orders in the market than can seemingly be filled. Bleach for prompt shipment from works has been quite active, and buyers have found it difficult to cover generally. For 1918 business 2¼c. is generally quoted as a minimum price but 2⅛c. is named as one contract figure.

Chlorate of Potash.—As we write the 1918 price has not been publicly announced. There is much speculation as to the figure. It is generally assumed that it will be somewhat below 40c. The second hand market has been quiet and generally easy during the two weeks. Sales have occurred at 42c. and even 44c., but some firms anxious to dispose of contract material have offered several hundred kegs at even lower figures.

Acids.—As a result of the extensive government requirements and the fact that the acid production is now much oversold, the market for sulphuric acid has become almost nominal. There are offers reported from second hands, and these range from $38 to $40, buyers' tanks or drums returnable. *Oleum* has already reached the $60 level and promises to pass that point soon. *Nitric Acid* has not been so firm. As yet there has been no pronounced demand. Nitrate of soda has been easier, but sulphuric is higher and an important demand will no doubt send prices higher. *Muriatic acid* has after a period of quietness become quite scarce and prices are somewhat firmer.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, DEC. 26, 1917

Financial, Construction and Manufacturers' News

New Companies

THE ALLOY FOUNDRY & MACHINE COMPANY, New Rochelle, N. Y. Capital, $10,000. To operate a plant for the manufacture of castings. Incorporators: Arthur C. Wakeling, Walter F. Wollheim and Gustav C. Pansegrau, New Rochelle.

THE AMALGAMATED CORPORATION, Dover, Del. Capital, $335,000. To manufacture tools of various kinds.

THE AUTOMATIC SHELL-BORING MUNITIONS COMPANY, Philadelphia, Pa. Capital, $100,000. To manufacture dynamite, gunpowder and other explosives. Incorporators: Cyrus Hawkins, Samuel Hough and Russell H. Myers, Philadelphia.

THE BARNHARD FERTILIZER COMPANY, Frankfort, Ind. Capital, $100,000. To engage in the manufacture of fertilizers and kindred products. Incorporators: Clifton W. Cobee, Samuel L. Barnhard and Raymond E. Steward.

THE CAMBRIDGE FOUNDRY & MACHINE COMPANY, Cambridge, Ohio. Capital, $50,000. To operate a local plant. Mark A. Copeland is the principal incorporator.

THE CENTRAL PIGMENT COMPANY, Dover, Del. Capital, $250,000. To engage in a general mining business.

THE T. J. COOPER RUBBER COMPANY, INC., Jersey City, N. J. Capital, $75,000. To manufacture rubber tires. Incorporators: W. Metkiff, J. McLaren and R. Rudolph.

THE COSBY CHEMICAL COMPANY, Chicago, Ill. Capital, $150,000. To manufacture chemicals and allied products. Incorporators: G. H. and J. I. Childs and John H. Mulligan, Chicago.

THE CRAVIER FOUNDRY COMPANY, INC., Rochester, N. Y. Nominal capital, $5,000. To operate a local foundry. Incorporators: L. C. Graves, J. T. Cravier and T. Hanlon, Jr., all of Rochester.

THE DETROIT FUEL & FOUNDRY SUPPLY COMPANY, Detroit, Mich. Capital, $75,000. To engage in the manufacture of foundry supplies, etc. Incorporators: Webster L. Sallee, John T. Hornbrook and Frank I. Cornwall, Detroit.

THE DETROIT MICA COMPANY, Detroit, Mich. Capital, $10,000. Incorporators: James E. Burgess, C. A. Bromley and C. J. Thorp, Detroit.

THE FORE CHEMICAL WORKS, INC., Jersey City, N. J. Capital, $475,000. To manufacture chemicals and kindred products. Incorporators: R. E. Breed, M. W. Alexander and U. M. Fleischman, all of Wilmington, Del.

THE FOUR GASOLINE COMPANY, Dover, Del. Capital, $100,000. To extract gasoline from natural gas, etc.

THE GREAT NORTHERN STEEL & IRON COMPANY, Duluth, Minn. Capital, $500,000. To engage in the mining, smelting, reducing and refining of metals and the manufacture of iron and steel products. Incorporators: E. C. Kennedy, Frank L. Swan and N. C. Johnston, all of Duluth.

THE DORRITE INSULATION COMPANY, INC., 188-192 Culver Avenue, Jersey City, N. J., has been incorporated with a capital stock of $200,000. Harry A. Dorr is vice-president; Robert D. Radcliffe, Jr., treasurer, and R. D. Adams, secretary. A large two-story brick building is now being equipped. The factory will be in operation about Feb. 1, 1918. The company proposes to manufacture "Dorrite," an insulating material, which may be molded, stamped or pressed into all special or commercial sizes and shapes for all electrical insulating uses.

THE L. H. BUTCHER COMPANY, New York and San Francisco, has been incorporated under the laws of New York to manufacture and deal in colors, chemicals, minerals and industrial ores. Principal offices, 100 William St., New York. Officers: S. L. Schwartz, president; J. E. Schwartz, vice-president (both of San Francisco); Virgil G. Thomas treasurer and secretary, New York.

THE HIGH SPEED STEEL PRODUCTS CORPORATION, New York. Capital, $27,500. Incorporators: A. F. McCabe, P. H. Butchorn and A. E. Moore, 37 Wall Street.

THE INTERCONTINENTAL PRODUCTS CORPORATION, New York. Nominal capital, $5,000. To manufacture chemicals, dyestuffs and kindred products. Incorporators: D. D. H. Minassian, M. J. Gourland and L. Haim, 253 West Seventy-second Street.

THE INTERNATIONAL NITRO-FIX COMPANY, Wilmington, Del. Capital, $250,000. To manufacture chemicals, nitrogen compounds, etc. Incorporators: William S. Hilles, La-Penne Guenvuer and R. J. Brenneisen, all of Wilmington.

THE INTERNATIONAL STEEL TUBE & ROLLING MILLS, INC., Cleveland, Ohio. Capital, $2,500,000. To operate a plant for the manufacture of tubing, etc. Incorporators: O. R. Grimmesey and C. H. Hopkins.

THE JAHANT FOUNDRY & HEATING COMPANY, Akron, Ohio. Capital, $100,000. To operate a local plant. Incorporators: H. F. McGill, Philip B. Treash, A. H. Cumming, C. Blake McDowell and F. France, Akron.

THE JOHNSON-PYROLIN CORPORATION, Washington, D. C. Capital, $1,000,000. To manufacture fireproofing and fire-resisting paints, oils, etc. Incorporators: T. G. Brady, J. H. Huston and E. R. Turner, all of Washington.

THE KYUNE COMPANY, Wilmington, Del. To engage in the manufacture of iron products. Incorporators: K. E. Longfield, F. D. Buck and M. L. Horty, all of Wilmington.

THE L. J. LEWERY COMPANY, New York. Capital, $200,000. To deal in iron and steel products. Incorporators: S. B. Howard, George V. Reilly and A. W. Britton, 65 Cedar Street.

THE LIBERTY METAL PRODUCING COMPANY, Westcliffe, Col. Capital, $400,000. To conduct a general mining business. Incorporators: Jacob Abelson, D. W. Kahane and I. H. Kuhn.

THE LUMMUS MACHINERY COMPANY, Spartanburg, S. C. Capital, $10,000. To manufacture machinery of various kinds. Incorporators: J. L. Lummus and Robert E. Carter, Spartanburg, and A. L. Lummus, Saluda, N. C.

THE METALOID COMPANY, Bayonne, N. J. Capital, $25,000. To manufacture chemicals and allied products. Incorporators: Thomas Brady, Joseph E. Gerry and James Benny, all of Bayonne.

THE MIAMI ZINC & LEAD SYNDICATE, Miami, Okla. Capital, $5,000,000. To engage in a general smelting and refining business. Incorporators: C. C. Slaughter, Jr., L. P. Gamble, Dallas, Tex.; E. P. Mix, W. H. Logan and D. Rice, Miami, and W. F. Felker and J. E. Felker, Rogers, Ark.

THE NATIONAL BEARINGS COMPANY, Dover, Del. Capital, $100,000. To manufacture ball bearings, etc. Incorporators: C. L. Rimlinger, M. M. Clancy, Wilmington, and C. M. Egner, Elkton, Md.

THE NEW ENGLAND GRAPHITE COMPANY, Augusta, Me. Capital, $200,000. To mine for graphite, talc, mica, etc., produce gas, oil and kindred products.

THE PAN-AMERICAN MANGANESE CORPORATION, Dover, Del. Canital, $3,500,000. To engage in the development of iron and manganese properties.

THE PARAFFINE COMPANIES, INC., Dover, Del. Capital, $15,500,000. To manufacture paints, paint materials and allied products.

THE PERCHLORATE EXPLOSIVES CORPORATION, Poughkeepsie, N. Y. Canital, $2,100,000. To manufacture chemicals, explosives, etc. Incorporators: C. W. H. Arnold, L. Bedell and H. B. Vosburg, Pourhkeepsie.

THE SAFETY FRAGILE ARTICLE CARRIERS COMPANY, New York. Capital, $500,000. To manufacture paper boxes, etc. Incorporators: Henry S. Gilbert, John P. Phillan, New York, and V. T. Casson, Philadelphia, Pa.

IRA L. SLOMON, INC. New York. Capital, $30,000. To manufacture varnishes, shellac, rubber, etc. Incorporators: S. Moore and M. L. and L. Slomon, 164 East Thirty-fifth Street, New York.

THE SOUTHERN PRODUCING & REFINING COMPANY, Dover, Del. Canital, $3,000,000. To engage in the production and refining of oil.

THE STANDARD METALS REDUCTION COMPANY, Chicago, Ill. Capital $2,000,000. To mine for ores and minerals of all kinds. Incorporators: J. E. Harner, James H. Ayem and T. T. Watson, all of Chicago.

THE STODDARD UNION COMPANY, INC., New York. Canital $100,000. To operate foundries. Incorporators: Earl O. Aspdin, Albert Hild and Frank B. Potterton, New York.

THE TORWILLIGER EQUIPMENT COMPANY, Dover, Del. Capital, $50,000. To operate a plant for the manufacture of engines, motors, boilers and kindred equipment.

THE UNITED STATES POTASH PRODUCTS COMPANY, White Plains, N. Y. Capital, $5,500,000. Incorporators: D. T. Connet, White Plains; J. F. Roach and C. E. Bahn, all of New York.

THE UNITED SUGAR COMPANY, Salt Lake City, Utah. Capital, $1,100,000. To manufacture sugar and all byproducts thereof. Incorporators: F. M. Lyman, Jr., A. J. Gillis, L. C. Wooley, D. F. Thomas and H. A. Strauss, Salt Lake City.

D. A. VANHORNE & COMPANY, INC., Newark, N. J. Capital, $75,000. To manufacture glassware of all kinds. Incorporators: G. and Edward B. Vanhorne and H. T. Stetson, Newark.

THE VITHUMUS COMPANY, Norfolk, Va. Capital, $975,000. To operate a plant for the manufacture of fertilizers, etc. Incorporators: R. W. Gamble, R. C. Taylor and George M. Payne.

THE WAY-CLEANSE CORPORATION, New York. Capital, $5,000,000. To manufacture special machines for the cleaning of streets, railway tracks, etc.

FRED WETZEL & COMPANY, New York. Capital, $10,000. To manufacture chemicals and kindred products. Incorporators: F. Wetzel, C. and R. Toepfer, 305 West 134th Street.

THE WYOMING SULPHUR & REFINING COMPANY, Chicago, Ill. Capital, $2,000,000. To manufacture sulphur and chemical products. Incorporators: T. W. Cole, Chicago; K. S. Wilson and M. Luce, Oak Park, Ill.

Construction and Operation

Alabama

ENSLEY.—The National Steel Products Company has acquired property on Eighth Avenue, Bessemer, and plans for the immediate construction of a plant for the manufacture of guard rails, switches, steel castings and allied railroad products. The proposed plant is estimated to cost about $25,000 and is expected to be ready for operation early in March 1918. R. S. Bohannon is president, and George A. Millar, vice-president.

BIRMINGHAM.—The Tennessee Coal, Iron & Railroad Company is considering the construction of additions to its steel plant at Fairfield, to consist of new plate and angle mills, machine shop, forge and foundry, and other structures to be devoted to the manufacture of machinery and parts for ship construction. A new open-hearth furnace and converter will be installed in the company's plant at Ensley.

MUSCLE SHOALS.—Definite steps have been taken by the United States Government in the construction of its proposed plant at Muscle Shoals, near Sheffield, to be devoted to the manufacture of ammonia, nitric acid and other chemicals employed in the manufacture of explosives. The Government has announced that the cyanamid process of air fixation will be adopted, and for this purpose the American Cyanamid Company has surrendered its process patents, data, chemicals, etc., for the duration of the war. The first unit of the new plant is expected to be completed and ready for operation within the next six months, the entire works involving an expenditure of approximately $30,000,000. Frank S. Washburn, president of the American Cyanamid Company, will be the chief adviser of the Government in the construction of the new nitrate plant. Power for the operation of the works will be furnished by the Alabama Power Company, which is under a three-year contract with the Government to that end. A new company has been formed to be known as the Air Nitrates Corporation. The officers are Frank S. Washburn, president; K. F. Cooper, vice-president; A. E. Bond, secretary, and S. M. Boyce, treasurer. The offices of the company are at 511 Fifth Avenue and 360 Madison Avenue New York. This company will act as agent of the Ordnance Department in the construction of the new plant. The officers are at the head of the American Cyanamid Co.

Two thousand two hundred acres of land lying at the foot of Muscle Shoals and at the end of the Florence River bridge at South Florence has been selected as the most desirable site, and options have been secured on practically all of the land. The work of laying railway side-tracks has been under way for a week. Several thousand feet have been laid, and the work of laying more track is being rushed.

It is said that when the Government discovered that there was but little nitrate in the country and that great quantities must be had, the situation was viewed with

alarm. The officers and engineers of the American Cyanamid Co. were called upon for help, and at once showed their patriotism by volunteering to help in every way possible, giving their services free of charge in assisting in the building of a great nitrate plant and giving the Government the use of their valuable information.

It is stated that while the great dam is being built, and as soon as the nitrate plant is ready for operation, power to the extent of 30,000 horse-power will be secured from the Alabama Power Co., and that a steam plant to be erected on the site will also furnish 30,000 horse-power.

The entire plant will be so constructed that the power from the Muscle Shoals hydro-electric development may be used as soon as it is ready.

The statement has been made that the great plant will be rushed to completion and that by the first of July munitions from the nitrate will be on the way to France.

The site selected is especially desirable. It lies about 100 feet above the waters of the beautiful Tennessee and has perfect drainage. Railroads extending to the north, south, east and west pass through it, and river transportation may be had to all points down the Tennessee and points on the Ohio and Mississippi rivers.

California

LOS ANGELES.—The United Power Company has acquired property in the San Gabriel Canyon, formerly held by the Electric Power Company, and is planning for the erection of a new power plant at Iron Fork.

McKITTRICK.—The Associated Oil Company is having plans prepared for the installation of a new dehydrating plant on its Delmonte lease in the McKittrick field.

RICHMOND.—Construction has been commenced on a new plant on a site recently acquired from the East Shore Company by the Visayan Refining Company. The property has a deep-water frontage, and the new works will be devoted to the refining of copra.

SAN FRANCISCO.—The Judson Manufacturing Company has taken out a building permit for the construction of extensive additions to its refining mill, which extends from the foot of Park Avenue to the Oakland line. The company has recently received a number of large contracts, and the additions are to provide for increased capacity.

Connecticut

BRISTOL.—The Bristol Brass Company, Forestville, near Bristol, has commenced the construction of an addition to its plant on Broad Street. The extension will be used for metal reclaiming and allied operations.

WATERBURY.—The Connecticut Brass & Manufacturing Company, a Delaware incorporation, recently perfected to take over the Connecticut Brass Corporation, West Cheshire, and the Piling Brass Company, Waterbury, has taken out authorization papers to operate in Newark. J. C. Lyon, Jr., 61 Broadway, is representative.

Delaware

NEWARK.—A portion of the salicylic acid plant of the duPont Powder Company was destroyed by fire on December 14, with loss said to be about $100,000.

NEWCASTLE.—Fire on December 6 destroyed a section of the plant of the Wilmington Fibre Specialties Company, which was engaged on Government contracts. The loss is estimated at $300,000.

NEWCASTLE.—Fire on December 12 destroyed a portion of the shell-loading plant of the Bethlehem Steel Company, near Newcastle, with loss estimated at about $100,000.

NEWCASTLE.—The Penn-Seaboard Steel Corporation has acquired property adjoining its Baldt works, about 85 acres, and is said to be planning for the construction of a new steel plant.

Florida

JACKSONVILLE.—The Vulcan Iron Works has acquired property on East Bay Street, for a consideration of about $10,000, and is planning for the construction of a large new plant.

Illinois

CHICAGO.—The Nubian Paint & Varnish Company, LeClaire Avenue, has acquired property adjacent to its works, and is planning for the erection of additions to provide for increased capacity. The property was purchased for a consideration of $25,000.

CHICAGO.—Swift & Company has completed arrangements for the purchase of a tract of 26,175 acres of land in West Hammond, and is having plans prepared for the construction of a new fertilizing plant to comprise a group of one-story concrete and brick structures. The entire works, when completed, are estimated to cost about $500,000.

ROCKFORD.—The Rockford Milling Machinery Company is making rapid progress in the construction of a new two-story addition, about 35 x 120 feet, at Harrison Avenue and Eleventh Street, to cost about $25,000.

E. ST. LOUIS.—The Excelsior Tool & Machine Co. is extending its plant and adding to its foundry. New pattern storage and pattern shop buildings will also be erected. A large core oven and ten-ton and two-ton cranes will be required.

Indiana

LAFAYETTE.—The Barnhard Fertilizer Company, recently incorporated at Frankfort with a capital stock of $100,000, has acquired the plant and business of William Kalberer, 906 Sycamore Street, and is planning for extensive improvements and alterations. The consideration was $15,000. S. L. Barnhard is president of the company.

GREENCASTLE.—The American Zinc Products Company, which recently purchased the old Western Tin Plate Mill, has acquired 60 acres of land adjoining the works and is planning for the construction of a new ten-mill plant. The works will give employment to about 500 hands.

MUNCIE.—The Standard Oil Company has acquired property on West Charles Street, and is having plans prepared for the construction of a new three-story brick plant.

Louisiana

CONVENT.—Fire recently destroyed the sugar manufacturing plant of the Louis Himel Planting & Manufacturing Company at its Elyisa plantation, with loss estimated at $100,000.

Maine

PORTLAND.—The Berlin Mills Company has announced that arrangements have been perfected for its consolidation with the Burgess Sulphite Fiber Company, the new organization to be known as the Brown Company. It is planned to increase the capacity of its paper and paper products mills. H. J. Brown is president.

Maryland

BALTIMORE.—Fire recently destroyed a portion of the Mount Winans works of the Maryland Glass Manufacturing Company. It is said the damaged section will be immediately rebuilt.

Massachusetts

BOSTON.—Contract has been awarded by F. E. Atteaux & Company, manufacturers of chemicals, dyestuffs, etc., for the erection of a new two-story reinforced-concrete factory building, about 65 x 170 feet, in South Boston. The Turner Construction Company, Boston, is the contractor.

Michigan

MENOMINEE.—The Menominee Electric Manufacturing Company is taking bids for the erection of four one-story additions to its works to cost about $60,000.

MUSKEGON.—Rapid progress is being made in the construction of the new plant of the Muskegon Aluminum Foundry Company, Clay Avenue and Ninth Street, and it is expected that the works will be ready for the installation of machinery and equipment within the next three weeks. A. E. Johnson heads the company.

Missouri

ST. LOUIS.—The Pontiac Iron & Land Company is planning for the erection of a pig iron furnace with initial capacity of 40 tons, on property recently acquired in Wayne County. The company owns a tract of about 20,000 acres in this district and plans for extensive operations. J. F. Lindsay, St. Louis; Ira J. Hoover, Waterloo, Ia., and C. H. Plant, San Antonio, Tex., head the company.

ST. LOUIS.—Fire recently destroyed a portion of the plant of the Liquid Carbonic Company, 3400 Bernard Street, with loss estimated at $50,000.

New Jersey

JERSEY CITY.—The Interstate Chemical Company, 657 Garfield Avenue, manufacturer of chemicals and allied products, has taken out a building permit for the construction of a new addition to its plant at 673 Garfield Avenue.

HARRISON.—The E. I. duPont de Nemours Company has announced that effective January 1, 1918, it will discontinue the sale of acids and chemical products of its Harrison works through the National Oil & Supply Company, and will establish a branch for this purpose at 272-78 Passaic Street, Newark.

NEWARK.—The Block Chemical Works has acquired the property of the Berkeley Brick Company, Berkeley Heights, N. J., for a consideration said to be $25,000, and is planning to use the works as an addition to its plant.

NEWARK.—The United Color & Pigment Company is having plans prepared for the construction of a new three-story brick factory and a new one-story brick power house, to cost $54,212 and $10,572, respectively. Percy B. Taylor, Essex Building, is the engineer.

MORRISTOWN.—Charles Butters, of Oakland, Cal., has acquired property consisting of 10 acres at the junction of the Morristown & Erie Railroad and the Malapardis branch, and is planning to commence work immediately on the erection of a new aluminum bronze works.

JERSEY CITY.—The Air Reduction Company has taken out a building permit for the erection of a new one-story steel factory addition to its plant at 171 Pacific Avenue.

BAYONNE.—The Southern Cotton Seed Oil Company, East Twenty-second Street, has had plans prepared for alterations and extensions in its plant to cost about $8,000.

CAMDEN.—Wilckes, Martin & Wilckes Company, 135 Williams Street, manufacturer of chemicals, has awarded a contract for the construction of two new additions to its plant, one and two-story, about 110 x 134 and 30 x 100 feet, respectively. J. H. O'Leary, 500 Bloomfield Avenue, Passaic, is the contractor.

IRVINGTON (NEWARK).—The Irvington Varnish and Insulator Company, 218-232 East Speedway Avenue, has taken out a building permit for the erection of a new one-story brick factory, to cost about $25,000.

NEWARK.—The Block Chemical Works of Newark, N. J., has purchased the Berkeley Brick Company plant, located on the Lackawanna Railroad, at Berkeley Heights, N. J. The principal building is 36 x 308 of brick, steel and concrete construction with a large stack. The purchase was made through the Factory Exchange of New York. The Block Chemical Works is to completely equip this plant and not only require steam-producing machinery, but must provide for their private water supply and the apparatus necessary to produce their chemicals. We understand that their principal product is to be barium chloride.

NEWARK.—The Butterworth-Judson Company, Avenue R, manufacturer of chemicals, is planning for the erection of two new additions to its plant, about 50 x 55 feet, one-story, to cost $10,000, and a one-story machine and pipe shop, 50 x 90 feet, to cost $8,000.

NEWARK.—The Eclipse Tanning Company, 119 Sussex Avenue, is having plans prepared for the construction of a new factory building, about 100 x 200 feet, on the southwest corner of Sussex Avenue and Day Street. The structure will cost about $22,000.

ROOSEVELT.—Fire, on December 4, completely destroyed the nitric acid department of the Armour Fertilizer Works, with loss estimated at about $20,000. The destroyed portion of the plant will be immediately rebuilt.

SOUTH RIVER.—Fire recently destroyed the plant of the Para Products Company, manufacturer of rubber goods. The destroyed structure was about 100 x 200 feet, and it is said that chemicals used in the manufacture of the company's products were the cause of the blaze.

TRENTON.—The Joseph Stokes Rubber Company, Taylor Street, has awarded a contract to Edward LaRue, 52 South Hermitage Street, for the erection of a one-story addition to its plant.

TRENTON.—The National Carbon Company, 26 West State Street, has filed notice of the dissolution of the company.

Virginia

ALEXANDRIA.—The United States Government, Department of Agriculture, has awarded a contract for the construction of an addition to its chemical laboratory at Arlington Farm, near Rosslyn. Estimated cost of the structure will be $13,800.

New York

PORT RICHMOND, S. I.—The Standard Oil Company has acquired property on Richmond Avenue, adjoining its plant, and is planning for the erection of additions to provide for increased capacity.

LAUREL HILL, L. I.—The General Chemical Company, Washington Avenue, has awarded a contract for the construction of a new one-story addition to its local laboratory, to cost about $8,000. Leddy & Moore, 105 West Fortieth Street, New York, are the contractors.

YONKERS—The National Sugar Refining Company, Main Street, has filed plans for the construction of a new one-story brick addition to its plant, about 44 x 50 feet.

ROCHESTER.—A new one-story concrete and steel foundry addition, about 72 x 80 feet, will be erected by the Gleason Works, University Avenue. The company has taken out a building permit for the structure, which is estimated to cost $12,000.

BUFFALO.—The National Aniline & Chemical Company, Lee Street, is planning for the immediate construction of a new three-story brick factory building to cost $88,500.

North Carolina

JAMESTOWN.—The Caroline Pyrites Ore Company, recently organized with a capital of $100,000, is planning for the operation of its proposed new works at Gardner Hill. The machinery and equipment installation is estimated to cost $75,000.

Ohio

CARTHAGE.—The Pollak Steel Company has had plans prepared for the construction of two new additions to its plant, comprising a one-story foundry building, about 200 x 300 feet, and new drafting building. Contract for the latter structure has been awarded to the M. Marcus Building Company, Carthage.

MARIETTA—The Nye Foundry Company has completed arrangements for the removal of its foundry to West Spring Street, Columbus, Ohio, and is planning to double the capacity of the present plant. About 200 hands will be employed at the new location. B. H. Nye is general manager of the company.

SANDUSKY—The American Crayon Company is considering the acquirement of 10 acres of land in the extreme southeast corner of the city, as a site for its proposed new picric acid plant.

WARREN—M. A. Garvey and L. J. Garvey, Sharon, are planning for the establishment of a brass foundry in the old Day-Ward plant on North Park Avenue. It is the intention of the company to construct a plant of its own on property now under consideration. M. A. Garvey is manager.

Oklahoma

BARTLESVILLE—The United States Government has announced that the Bureau of Mines is planning for the construction of one of its experimental stations for the investigation of problems relating to the petroleum and natural gas industries, on a local site.

Pennsylvania

HEIDELBERG—Fire recently destroyed a portion of the plant of the Ætna Chemical Company at Heidelberg, near Pittsburgh, with loss estimated at $250,000. The fire was caused by an explosion, the plant being engaged in the manufacture of T.N.T.

KITTANNING.—Plans are being made by the Carbon Steel Company for the erection of two open-hearth furnaces on a site now under consideration, each furnace to have a capacity of about 100 tons of pig billets daily. This company recently acquired the property of the Kittanning Iron & Steel Company.

LEBANON—The Lebanon Blast Furnaces, operated by the E. J. Lavino Company, have suspended operations for relining and improvements, and it is expected that the work will be completed by the first of the year. These furnaces are devoted to the production of ferromanganese.

PHILADELPHIA—The Gorgas-Pierre Manufacturing Company, 144 East Allen Street, manufacturer of oils, etc., has awarded a contract for the construction of a new three-story concrete addition to its plant, about 75 x 156 feet to cost $50,000. The Turner Concrete Steel Company, 1713 Sansom Street, Philadelphia, is the contractor.

PITTSBURGH—Extensive alterations and improvements are being made in the plant of M. Streng's Sons Company, 1306-46 River Avenue, and the company is also planning for the construction of a new addition in which furnaces will be installed for the reclaiming of metals.

CANONSBURG—E. W. Edwards and associates, Cincinnati, Ohio, have taken over the plant of the Canonsburg Steel & Iron Works, and are planning for extensive additions to increase the capacity. The consideration is to be about $600,000.

MONONGAHELA CITY—The Monongahela Steel & Iron Company is perfecting arrangements for the construction of a new 36-furnace plant in Paden City, W. Va. Thomas Watson, Pittsburgh, is secretary and treasurer for the company.

ST. MARY'S—The Speer Carbon Company and the Stackpole Carbon Company are each installing two branches with vertical retorts for calcining petroleum coke. The Russell Engineering Company of St. Louis is making the installations.

Tennessee

KNOXVILLE—Construction of extensive additions to the plant of W. J. Oliver Company are being rushed to completion. New machinery has been ordered and will cost about $250,000. The plant is specializing in the production of six-inch shells for the Government, and will have a capacity of 1500 shells daily.

NASHVILLE—It has been reported that the du Ponts are planning the establishment of a million dollar explosive plant near Nashville. 2500 acres having been bought for a site. The report has not been verified by the du Pont Co.

Texas

BROWNWOOD.—The Gotebo Oil & Refining Company has commenced the construction of a large new local refinery on a site just south of the city. It is expected that the first unit of the plan will be completed and ready for operation within thirty days.

Utah

HONEYVILLE.—The Utah-Idaho Sugar Company has acquired a tract of 120 acres of land and is reported to be planning for the construction of a large new sugar plant.

SALT LAKE CITY.—The Utah Oil Refining Company is planning for the construction of extensive additions to its plant, to include a new paraffine works to cost $50,000; new tank to have a capacity of 1,500,000 gal, to cost $35,000, and the doubling of the present capacity of the power house. Headquarters of the company are at Fourth Street West and Ninth Street North. J. C. Howard is general manager.

SALT LAKE CITY—The Cedar Butte Oil Company is having plans prepared for the erection of a large reduction plant at its oil properties at Whiterocks.

Washington

SEATTLE.—The Alaska Gastineau Mining Company, Juneau, Alaska, has announced that a large new steel plant will be constructed on the Puget Sound which will involve an expenditure of approximately $25,000,000. The first unit of the plant will require an investment of $9,000,000, and work will be started on the plant within 90 days. Mr. Bart L. Thane is general manager of the company. W. H. Crocker, H. Fleischhacker, and S. F. B. Morse, San Francisco, Cal., are also interested in the project.

SEATTLE.—The Seattle Smelting Co., Inc., has completed its plant and is now producing ferromanganese. One three-phase unit capable of producing six tons of alloy per day has been installed and others ordered. Other ferroalloys may be produced later.

West Virginia

WHEELING.—The Superior Glass Manufacturing Company has recently completed the erection of a new addition to its plant to provide for increased capacity. The works were formerly occupied by the Haskins Glass Company, and when acquired by the Superior company, extensive improvements were made.

HUNTINGTON.—The Huntington Steel Products Company, specializing in the manufacture of munitions, is planning to increase the capacity of its plant.

HUNTINGTON.—L. H. DePaul, Foxboro, Mass., and associates are considering the erection of a large new local chemical plant, to be devoted to the manufacture of salycilic acid from sawdust.

Wisconsin

MADISON.—Fire recently destroyed a portion of the plant of the Southern Foundry Company with loss estimated at $50,000. The company was engaged in the manufacture of materials for munition plants.

MILWAUKEE.—The George H. Smith Steel Casting Company, 500 Clinton Street, is making rapid progress in the construction of a large new addition to its foundry.

MILWAUKEE.—The new plant of the General Steel Company near lake shore has commenced partial operations. The works consist of a large machine shop, mill building, storage building, and smaller shop structures, and the remainder of the machinery is now being installed. It is expected that the plant will run at full capacity within thirty days. The product of the works will be a high-grade electric steel. Harry Weidenthal is superintendent.

Manufacturers' Catalogs

E. I. DUPONT DE NEMOURS & COMPANY, together with its associates—the DuPont Fabrikoid Co., DuPont Chemical Works, the Arlington Company and Harrisons, Inc.—have issued a new products book, listing all the products of the above concerns and describing their uses. The head offices of the company are at Wilmington, Del.

THE BARRETT COMPANY, 17 Battery Place, New York City, has issued a new booklet on the source, production and use of sulphate of ammonia.

TATE-JONES & COMPANY, Pittsburgh, Pa., has issued Bulletin No. 160, giving a complete description of its recuperative gas-oven furnaces for the heat-treatment of steel.

CONDENSITE COMPANY OF AMERICA Bloomfield, N. J., has issued a new booklet, describing its various molding preparations and other phenolic condensation products.

LINK BELT COMPANY, Chicago, Ill., has issued a new bulletin entitled "The Ideal Drive for Clay Working Machines," giving many illustrations of the uses of link belts.

WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, East Pittsburgh, Pa., has issued Catalog 30, covering the company's complete line of direct-current motors and generators for industrial service.

Other New Publications

DETERMINATION OF MOISTURE IN COKE. A. C. Fieldner and W. A. Selvig. A bureau of mines technical paper, No. 148. Obtainable from the Bureau of Mines, Washington, D. C.

GOLD, SILVER, COPPER AND LEAD IN SOUTH DAKOTA AND WYOMING, in 1916. By Charles W. Henderson. U. S. Geological Survey report obtainable from the U. S. Geological Survey, Washington, D. C.

ANNUAL REPORT OF DIRECTOR OF BUREAU OF MINES, for year ending June, 1917, issued by Bureau of Mines, Washington, D. C.

Manufacturers' Notes

THE AMERICAN CHEMICAL & OZOKERITE Co. has removed its Chicago offices to 7323 Woodlawn Avenue, where the manufacturing plant is located.

THE RAYMOND BROS. IMPACT PULVERIZER Co., of Chicago has appointed the Dry Milling Engineering Co., 202 Boston Building, Denver, Col., western agents for its pulverizing machinery. The latter concern is headed by William B. Senseman and it will also represent the Buckeye Dryer Co., London, Ohio, the Dust Recovering & Conveying Co. of Cleveland and the Quigley Furnace Specialties Co. of New York. Mr. Senseman has been connected with Raymond Bros. for the past eight years. The Dry Milling Engineering Co. is a newly incorporated concern.

THE JONATHAN BARTLEY CRUCIBLE CO. of Trenton, N. J., manufacturers of crucibles and retorts, has engaged F. P. Welton of Stamford, Conn., to represent them in New England and Canada.

THE DIAMOND POWER SPECIALTY COMPANY of Detroit, Mich., is planning to market on a large scale a calorized metal known as Insuluminum, a description of which was given in our issue of Oct. 15, 1916, p. 498. A large plant has been built for its manufacture for such uses as soot blowers, superheater tubes, carbonizing boxes, annealing boxes, etc.

GANNESTAD & JACOBSEN, engineers, have moved their Pittsburgh headquarters to the B. F. Jones Building, where larger quarters are available. The firm is engaged in the designing of iron and steel and other industrial plants and special machinery.

Outlook for Water-Power Legislation

IN his message to the Congress last December the President said:

> "It is imperatively necessary that the consideration of the full use of the water power of the country * * * should be immediately resumed and affirmatively dealt with at the earliest possible moment. The pressing need of such legislation is daily becoming more obvious."

By emphasizing the "full use of the water power of the country" and the "pressing need" which is "daily becoming more obvious," the President shows his appreciation of the fair demands of all sections of the country and condemns the delay in legislation which has brought us to a state of pressing need for power. The government, being temporarily in the business of waging war, is suddenly brought to a realization of a condition which industry and private business have long since recognized.

Aside from Niagara and other projects that might be developed on boundary streams, which must be dealt with by international treaty, there are internal sources of water power subject only to our own legislation. These are upon navigable streams, public lands and national forest reserves. By our system of national organization the control of these three sources is vested in three separate departments of the government, viz., War, Interior and Agriculture respectively. This in itself is a complication that has proved a formidable barrier to progress in federal legislation, for hitherto it has seemed necessary to initiate special bills for each department in both houses of Congress.

It may be considered a stroke of policy, therefore, on the part of the Administration to attempt to surmount past obstacles by introducing in the House a new bill which has been drafted under the direction of the Secretaries of War, Interior and Agriculture covering all internal water power development, and which they consider most "likely to secure extensive devlopment of this resource." A digest of this new measure is given on another page in this issue. The bill embodies the fundamental features of several bills previously introduced in Congress, and aims to avoid their defects. In this it is largely successful, although a few moot points will have to be settled before the bill is passed if it is to be productive of actual development.

The term "actual cost" is used without definition in that section of the bill which provides for the taking over by the government of any project at the expiration of the term of license. Unless this term is clearly and satisfactorily defined, it would be fruitful of controversy in the transfer of any project from the licensee to the government. Indeed, failure to define the term would defeat the purpose of the bill, for prospective licensees would not be inclined to invest in a project the

value of which is to be determined only by future agreement between the Federal Power Commission and the licensee, or by proceedings in equity in a federal district court. Other provisions of the bill which probably will be modified relate to the issuance of new licenses at the end of a fifty-year period, and to the possible confusion in federal and state regulation of the licensee's securities, rates and service. It is practically assured that the bill will pass the House almost without debate. At this writing no such certainty exists with respect to the Senate, but it is more than likely that that body will fall in with the Administration's plan.

It will be a matter for congratulation if Congress shall act intelligently and quickly in this matter. Surely that body of men must have shared with the rest of us the feeling of impotence in our recent coal shortage and transportation difficulty, most of which would not have existed if we had long since developed our water powers. No more striking example should be needed of the folly of using coal so extensively for lighting, transportation and power—exhausting a resource which can serve us but once and neglecting another that is inexhaustible. Our lack of extensive hydro-electric development has made necessary the employment of much labor and rolling stock in the mining and transportation of coal. Most of this labor could have been released for productive work in other industries, and the rolling stock would have been available for transporting food, munitions and supplies, if we had been foresighted enough to develop a resource just at hand. We should have been in worse straits but for the projects already developed in the West which are supplying railroads, mines and cities with power. Dozens of undeveloped sources of water power still remain in the West and in other parts of the country, placing on us the duty of exerting every legitimate effort to see that Congress does not fail the nation at this critical time.

Analyzing for Traces

IT is doubtless a truism to remark that when a scientist digs deeper into the unknown, he little knows the infinite possibilities of the knowledge he uncovers. By that same token, works' chemists and metallurgists will cordially welcome the acquaintance of a new branch of so-called "pure science," namely, "the spectroscopy of the ultra-violet." In this wise:

Many modern chemical and metallurgical products are pure—containing smaller impurities than the familiar "chemically pure" reagents—and are shipped as such in enormous quantities. The final processes in the refining of such materials demand intermediates, solutions, or melts of extraordinary purity, and of course the chemical control requires most precise analysis for minute traces of foreign bodies.

In the remelting of copper wire and scrap, the bath must be worked until the lead, introduced by pieces of lead-covered cable, is below a certain small fraction, depending upon the ultimate use of the copper. Or, take as another instance, the zinc sulphate solution from which electrolytic zinc is precipitated. This solution must be free of cadmium, iron and copper (among other elements), not nearly free, but really free. Since it takes an expert analyst about three days to make a cadmium determination, in the meantime the electrolyte has been electrolyzed! Not only this, but few chemists who are skillful enough or reagents which are pure enough to analyze for traces are available in war times.

Messrs. Hill and Luckey presented a paper before the last American Electrochemical Society meeting (METALLURGICAL AND CHEMICAL ENGINEERING, Dec. 1, 1917, page 659) showing how a spectrograph can be used for quick determinations of traces of lead in a copper bath, which analysis is necessary in the first instance cited above. The spectrum has also been adapted for the determination of coloring matter in wines, the detection of blighted wheat flour, nitrates in water, phosphorus in suspected poisoning, and in the analysis of sugar and essential oils.

These instances are only an indication of the future usefulness of the method. While qualitative spectrum analysis is familiar to elementary students, quantitative spectrum analysis is a comparative stranger to experts, and seems to be confined to the determination of very small amounts of material—less than ten parts per million. That is exactly what is required in many metallurgical and chemical processes, and further intensive research along this line will undoubtedly prove to be very stimulating and highly productive of badly needed "short cuts."

The Present and Future of Potash

A TRITE expression that has gained currency in recent months informs us that any one of a dozen or so commodities "will win the war." The range is wide—from sugar to coal, wool to sulphuric acid. The expression has lost much of its earlier force, and the idea which it conveys has become as preposterous as the thought that the war can be won by the simple expedient of "doing our bit." Both expressions should be dropped from our war vocabulary, because the facts are that no single commodity will win the war, and we are only deceiving ourselves if we think that "our bit," or anything short of our all, will be sufficient.

All this is parenthetical to a brief consideration of potash as a war mineral, which, if it will not "win the war," is nevertheless of vast economic importance. Practically all the potash used in this country has normally come from Germany. The elimination of that supply threw us upon our own resources to meet pressing needs. Accordingly we took stock of the possibilities, and produced potash from natural brines, alunite and silicate rocks, cement-kiln and blast-furnace dust, kelp, wood ashes, beet and cane molasses, and distillery waste. In other words, we have made every possible source yield some potash, although much of the present industry is on strictly a war basis, and probably cannot continue in normal times.

Natural brines have been the most productive of all domestic sources. Alkali lakes in western Nebraska have been made to support a large industry, recently described in this journal. This development may not be able to survive a return to normal conditions, although the prospects will be better if methods of operation are improved. Searles Lake, in California, on the other hand, bids fair to be a real factor in supplying a large part of our needs. But whatever the future of potash from brines, it is certain that these lakes afforded the most readily available supply in our emergency.

The extraction of potash from silicate rock has been

an attractive proposition on account of the abundance of the material. Potash forms nearly 3 per cent of the earth's crust, and there are several silicate rocks containing the compound to the extent of 10 to 15 per cent. But if the material is abundant it is also chemically combined in such form as to be difficult of extraction, so that actual production from this source has lagged; this, too, in spite of a vast amount of research and experimentation, as indicated in the bibliography we are now publishing. So abundant and widely distributed a resource, however, is not likely to remain unutilized, and it seems reasonable to contemplate the possibility of supplying therefrom a large part of the world's demand for potash. With this in prospect, the reader will find some impressive figures in the interesting article in this issue contributed by Mr. Washington, who tells the potash story of Italian volcanoes.

Recovery of potash from kelp, a seaweed of common growth along our Southern Pacific coast, is likewise a most interesting problem. In the past few years we have developed an industry in California in which the investment aggregates between three and four million dollars. This is a large investment in a business which, frankly, will not be profitable after the war if German potash is again imported at pre-war prices. If the war continues long enough, the cost of plants can be amortized and the business abandoned when competition again exists. But this is not a pleasant prospect; we would far rather see the industry firmly established on a sound technical basis and able to hold its own. One difficulty at present is that none of the operators is willing to conduct any research. They feel that it is their business to make potash while they can, at present prices, because they know the precarious nature of their industry. This is all right for the present, but not satisfactory for the future. Hence the greatest importance attaches to the government experimental kelp farm on the California coast, where the problems are being attacked in a scientific manner by the Department of Agriculture with an eye to the future stability of the industry. The chief problems are those of drying and distillation, coupled with recovery of all possible by-products from the latter process, such as tar, ammonia and combustible gases. The object of the farm and plant is to determine whether potash can be produced from kelp at a profit or loss. The results will give a fairly definite answer to the question of the importance of kelp as a source of potash after the war.

Restricted Steel Output

IT makes a poor showing indeed that the steel ingot production of the United States in 1917 was only about 42,000,000 tons, as just estimated by the American Iron and Steel Institute, against 41,400,000 tons produced in 1916, for there was new open-hearth steel-making capacity completed in 1916 to the extent of fully 4,000,000 tons, and a like amount of new capacity was added in 1917. As new construction began, and in only a very humble way, in June, 1915, the 1916 new capacity must have come in chiefly toward the latter part of the year, while the new construction in 1917 cannot have fallen preponderatingly toward the close of the year. Hence, with full operation of existing capacity throughout both years, the increase from one calendar year to the next should have been in excess of 4,000,000 tons, instead of only 800,000 tons.

The restriction in steel ingot output in 1917 was due chiefly to a shortage of pig iron. Whether under the most favorable operating conditions at the blast furnaces they could have produced enough pig iron to supply all the steel-making capacity is a question. What is well known is that the blast furnaces did not operate at capacity in 1917. Pig-iron production was about 800,000 tons less than in 1916, whereas there was much more capacity. From May 13, 1916, to the end of the year four new blast furnaces were blown in, and in 1917 there were 14 new blast furnaces completed, largely about the middle of the year, the 18 stacks being fully equal to a production of 2,000,000 tons of pig iron a year.

While it may be true that if the chief bar to full production of pig iron in 1917 had not existed various other minor influences might have been felt, the outstanding fact is that pig-iron production in 1917 was held at the low level shown because not enough coke was moved from the Connellsville coke region to the blast furnaces depending on the region. There was a decrease in that movement, from 1916 to 1917, of nearly 4,000,000 tons. As to the cause, there was much "passing the buck" during the year, chiefly between the operators and the railroads. The operators claimed car supplies were insufficient, the railroads rejoining that when more cars were furnished they were not loaded, whereupon the coke operators came back and asserted that in periods of enforced idleness their labor drifted away. Toward the close of the year they claimed they had much more labor than formerly, but car supplies were still poorer. Obviously a condition existed which required team work, and the United States Government has become the "big boss." At the end of the old year it took over the operation of the railroads and on Jan. 3 Warren S. Blauvelt, national coke administrator, addressed the coke operators of the Connellsville region at Uniontown, assuring them that full transportation facilities would be provided and insisting that there must be full production of coke or something would be done by Washington.

What is particularly distressing in the situation is that the deficit in coke supply, particularly as regards the conditions of the past few months, is less than the amount by which Connellsville coke shipments have decreased. If the region were shipping as much coke as in 1916 there would be a surplus of coke. The completion of by-product ovens has been such as to take care of the increase in blast furnace capacity.

It is to be hoped that relief as to supplies of Connellsville coke will be afforded very shortly. In another direction a measure of relief of no small consequence will be provided, as the by-product plant of 640 ovens at Clairton is nearing completion and may make its first coke by April 1, with full production of the 640 retorts not long afterward. Their expected output is 2,740,000 tons of coke a year, on the conservative estimate of a 67 per cent yield, with nearly 7000 cu. ft. of gas per ton of coke made, the gas in turn doing its bit to relieve the fuel situation, for all the coal consumed at the Clairton plant will be brought by water. As the coke will be distributed to the various blast furnaces by the Carnegie Steel Company's own interplant road the entire operation will be independent of the railroads.

Mill Pumping Systems: Frenier Pump Capacities

To the Editor of Metallurgical & Chemical Engineering

SIR:—I regret that, through an error in typing, the Frenier pump capacities appearing in your Dec. 1 issue were underestimated by the omission of the final "0" in each case. The table should have read:

Size, Inches	Specific Gravity of Fluid					
	1.000	1.100	1.200	1.300	1.400	1.500
	Tons per 24 Hours					
44 by 6 48 by 6 54 by 6	450	490	540	580	630	670
44 by 8 48 by 8 54 by 8	540	590	650	700	760	810
44 by 10 48 by 10 54 by 10	630	690	760	820	880	940

These capacities are based on moderate lifts, precise adjustment and maintenance of level of liquid in the box, and free discharge. If any one of these conditions is impracticable the figures should be reduced accordingly.

Denver, Colo.

Conversion Table: Pounds to Grams

To the Editor of Metallurgical & Chemical Engineering

SIR:—The accompanying table will serve as a convenient means of rapidly converting pounds avoirdupois into grams. The facility with which this operation may be performed will be quite apparent, but the following description will not be out of place:

In Table I, pounds avoirdupois (1 to 9) are indicated by figures in left-hand column. The metric units are indicated by headings along the upper border. One pound (avoirdupois) equals 453.5924 grams, or 45.359 decograms, or 453592.4277 milligrams.

TABLE I

POUNDS	GRAMS												
		KILOGRAMS	HECTOGRAMS	DECOGRAMS	GRAMS	DECIGRAMS	CENTIGRAMS	MILLIGRAMS					
1	0	0	4	5	3	5	9	2	4	2	7	7	
2	0	0	9	0	7	. 1	8	4	8	5	5	4	
3	0	1	3	6	0	. 7	7	7	2	8	3	1

3	.1875	85.048 580		.53	240.403 987	14		396.893 374
	.19	86.182 561		.54	244.939 911		.87	394.625 412
	.2	90.718 486		.55	249.475 835		.88	399.161 336
	.21	95.254 410		.56	254.011 760		.89	403.697 261
	.22	99.790 334	9		255.145 741		.9	408.233 185
	.23	104.326 258		.57	258.547 684		.91	412.769 109
	.24	108.862 183		.58	263.083 608		.92	417.305 033
4	.25	113.398 107		.59	267.619 532		.93	421.840 958
	.26	117.934 031		.6	272.155 457	15		425.242 901
	.27	122.469 955		.61	276.691 381		.94	426.376 882
	.28	127.005 880		.62	281.227 305		.95	430.912 806
	.29	131.541 804	10		283.495 267		.96	435.448 731
	.3	136.077 728		.63	285.763 229		.97	439.984 655
	.31	140.613 653		.64	290 299 154		.98	444.520 579
5		141 747 634		.65	294.835 078		.99	449.056 503
	.32	145.149 576		.66	299.371 002	16	1.	453.592 428
	.33	149.685 501		.67	303.906 927			
	.34	154.221 425		.68	308.442 851			

Along the lower border are indicated the numerical denominations, located in a manner that permits them to be used as multipliers or divisors for the pound unit values.

As an example, it is desired to know the value of 5.5 pounds in grams.

From the value opposite the index figure 5 read 2267.9621385, and then it is quite obvious that .5 would be one-tenth of the above amount, or

5. lb. = 2267.9621385 g.
.5 lb. = 226.79621385 g.

5.5 lb. = 2494.75835235 g.

Table II will serve the purpose of representing the value of decimal parts of a pound avoirdupois, varying by one-hundredths.

The value of 5.5 pounds in grams may be read direct from the table by shifting the decimals in the value opposite .55 pounds.

It will also be noted that the exact decimals representing the ounces in a pound are shown in the column of figures headed "Oz."

Determination of Phosphorus in High-Speed Steels

To the Editor of Metallurgical & Chemical Engineering

SIR:—The writer has the issues of METALLURGICAL & CHEMICAL ENGINEERING for Feb. 1, Dec. 1 and Dec. 15, 1917, before him, open respectively to the contribution of Mr. E. C. Kraus concerning determination of phosphorus in high-speed steels, the writer's comments thereon, and Mr. Kraus' reply to the writer.

From Mr. Kraus' own statement the vital points in his contribution are two in number. First, the elimination of tungsten without evaporation and subsequent "baking," and second, the elimination of interference of vanadium in the precipitation of phosphorus by reduction with sulphurous acid.

Regarding these two significant points of his contribution, it is common knowledge that WO_3 does not require "baking" to render it insoluble in an aqua regia solution, and that "baking" is resorted to only when silicon is to be determined, as well as tungsten and phosphorus, from the same sample-weight. Obviously, then, the only point for which credit could be claimed was the elimination of the interference of vanadium.

The contention of the writer in his comment appearing in the Dec. 1 issue of METALLURGICAL & CHEMICAL ENGINEERING was that credit for this time-saving procedure should go to two Bureau of Standards chemists. In looking over his files to ascertain the names of these chemists, the writer finds that he was in error when he stated that the article concerning investigations in the precipitation of phosphorus in the presence of vanadium appeared in METALLURGICAL & CHEMICAL ENGINEERING in 1913. The publication to which the writer had reference was *Technological Paper* No. 24 of the Bureau of Standards, written by J. R. Cain and F. H. Tucker, published May 17, 1913. The use of sulphurous acid in eliminating interference of vanadium in this determination is also incorporated in Standard Methods of Analysis as given in A. S. T. M. Year-book for 1915. Both of these publications antedate considerably Mr. Kraus' communication. The writer merely worked out the application of the procedure, as outlined by J. R. Cain and F. H. Tucker, to the method then in use, involving the separation of tungsten as a necessary preliminary to the determination of phosphorus.

Plattsburg, N. Y. W. T. SHEFFIELD.

* * *

To the Editor of Metallurgical & Chemical Engineering

SIR:—As I am somewhat interested in the recent discussion regarding the determination of phosphorus in high-speed steel, by W. T. Sheffield and E. C. Kraus, I wish to corroborate Mr. Sheffield's statement that his method was worked out in this laboratory during the fall of 1913.

While talking with Mr. Kraus last summer concerning his method I do not remember having made reference to a similar method of previous origin—a fact which I unintentionally omitted. However, we had been using Mr. Sheffield's method in this laboratory for some time before the article by Mr. Kraus was published. The sole purpose of this letter is to corroborate Mr. Sheffield's dates. O. L. VAN VALKENBURGH.

Crucible Steel Company of America,
Sanderson Bros. Works,
Syracuse, N. Y.

The pertinent facts being established, the discussion is closed.
—EDITOR.

Power from Coal

To the Editor of Metallurgical & Chemical Engineering

SIR:—I was very much interested in the article regarding power from coal, which was published under Readers' Views and Comments in your issue of December 1, 1917. The demand for power is beginning to exceed the supply, and every effort must be put forth to obtain it. When a condition of this kind occurs results may be expected in improving the efficiency of apparatus used for power generation.

With the present steam plants little more efficiency can be expected, except in the smaller plants. It is generally true that the small plant, up to 5,000 kw., as a rule, operates inefficiently. Much is being done to improve this, and it is probable that the next year will see great improvements in the average small plant. Increase of pressure and superheat over the existing standards, for these are more or less standard, will result in improvements in efficiencies of probably 10 to 12 per cent. The difficulties are more of a practical nature than otherwise, but the turbine and boiler builders are ready to make any reasonable increase.

In the system presented in the above named article it appears to me that thermal efficiency will be low because the temperature of the gases leaving the turbine will be high, and the expansion will not be as complete as with the steam turbine. Removal of the tar, which is a combustible, and production of ammonia, which requires the combining of nitrogen and hydrogen, will also tend to reduce the thermal efficiency. The inefficiency of the air compressors will be to some extent compensated for by using the cooling water in the steam boiler. This will also apply to the cooling water for the turbine bearings, and the other water-cooled parts. It is also probable that more steam will be generated than will be needed for the production of gas, since the heat content of the gas will be less than that of the steam. It is my opinion that, when all of the different conditions are thoroughly analyzed, it will be found that the gas engine of the reciprocating type is better adapted to transform the chemical energy of the gas into mechanical or electrical energy.

Reference may also be made to the mercury vapor boiler, but this would probably be too costly for electrochemical work.

A steam-power plant using turbines, proper temperatures, and the suitable apparatus to obtain maximum economy, when placed so that coal can be obtained at low cost, and supplied with an ample supply of cooling water, will, when operated with load factors characteristic of the electrochemical industries, supply power at a cost comparing with the best water-power rates.

Tug River Elec. Co.
Williamson, W. Va.

Canadian Metal Production.—The Canadian Department of Mines estimates the production of metals from Canadian ores for 1917 as follows: Copper, 113,000,000 lb.; nickel, 84,800,000 lb.; lead, 56,700,000 lb.; zinc, 31,000,000 lb.; gold, 17,000,000 oz.; silver, 23,500,000 oz. About 1,186,000 short tons of pig iron were produced and 1,735,000 tons of steel ingots and castings. The production of gold, silver, copper and coal was less than in 1916. The others mentioned were greater.

A New Water-Power Program in Congress

RECENT important developments in Washington indicate that the administration proposes to accomplish something definite in the development of the water power of the country. For several years past there have been independent programs in the House and Senate covering the development of water power on the public domain and on navigable streams, but due to a lack of co-ordination of the several governmental departments involved, nothing of consequence has resulted. Senate and House apparently have taken irreconcilable positions in the past. Both have passed measures, but neither has been able to agree with the other.

A part of the trouble is due to the complexity of our administration of internal affairs. The public domain is under the control of the Secretary of the Interior, except for forest reserves, which are controlled by the Secretary of Agriculture. Navigable streams, on the other hand, are under the control of the Secretary of War. Hitherto the attempt has been made to pass separate measures pertaining to water power on navigable streams and on the public domain, but the present effort is directed toward a co-ordination of the interests of the three departments.

On Jan. 4 the President held a conference with members of various committees of the House of Representatives, at which the passage of water-power legislation was urged. The personnel of the conferees is significant of the plan to harmonize the several factors concerned. Present at the conference were Thetus W. Sims, chairman of the House Committee on Interstate and Foreign Commerce, who has recently succeeded Judge Adamson in that position; Scott Ferris of Oklahoma, chairman of the House Public Lands Committee; Asbury F. Lever of South Carolina, chairman of the House Agricultural Committee, and Edward W. Pou of North Carolina, chairman of the House Rules Committee, as well as Finis J. Garrett, the ranking member of the House Rules Committee.

The President committed to the care of Representative Pou a copy of a new water-power bill, which will be known as the Administration bill, which attempts to co-ordinate water-power legislation proposed for several years past in both Houses of Congress not only on the public domain but in navigable streams and national forests. The result of the White House conference, it is authoritatively stated in Washington, will be that the House Rules Committee will bring in a rule peremptorily requiring the House of Representatives to vote on and pass water-power legislation at an early date.

The bill was drawn by Gen. Black and Col. Keller, of the Army Engineer Corps, representing the War Department; Edward C. Finney, water-power expert for Secretary Lane, and former Representative Lathrop Brown of New York, now a special assistant to Secretary Lane, representing the Interior Department, and O. C. Merrill of the Forest Service, representing the Agricultural Department, who compiled, several years ago, a mammoth report on water-power companies, their banking affiliations, etc.

Provisions of the Administration Bill

Although most of the delay in water-power legislation has been due to Congress, some of it has been due to opposing views held by members of the Cabinet. These views have now been reconciled in the new Administration Bill, which provides for a Federal Power Commission, to be composed of three cabinet officers—Secretary of the Interior, Secretary of Agriculture and Secretary of War. It provides for an executive officer of the commission, who shall be appointed by the President for a term of five years. It provides for the payment of rentals of not less than 10 cents per horsepower per annum, a feature to which there has never been objection of consequence by any interest. The commission is empowered to grant licenses to develop water power on public lands and navigable streams for a term of fifty years. At the end of the license period the licensee upon application for a new license shall remain in undisturbed possession until the proposed commission shall have done one of three things: First, issue a new license under laws at that time applicable; second, give license to a new licensee who shall pay for the original fair value of the property; or, third, take the property over upon paying for its fair value. Fair value is defined to include actual cost of property taken plus severance damages for all property not taken over and damaged by reason of severance. Fair value does not include any allowance for enhancement of values on land or water rights granted by the United States, or good-will, going value or prospective revenues. The bill provides for alteration, amendment or repeal by Congress, which expressly reserves such rights, but in case of alteration, amendment or repeal such shall not extend to the licensees who have exercised rights, or spent money under the bill.

At the presidential conference it was agreed that a committee of five members each from the House Committees on Interstate and Foreign Commerce, Agriculture, and Public Lands, fifteen in all, should be created to compose differences as to the various bills which have been under consideration heretofore in the House and to bring together the radical and the more moderate views as to water-power development. The Committee of Fifteen, it is felt in Washington, will be materially aided in its labors by the fact that after mature deliberation, advice and conference, President Wilson himself has presented a bill upon which he believes all can agree.

The Senate's Shields Bill

What is to take place in regard to water-power legislation in the Senate is not yet known, as that body passed the Shields bill on Dec. 14. This measure deals only with the development of water power on navigable streams, and has no reference to water power on public lands. The latter is in the hands of a separate Senate committee. The principal objects of the Shields bill are thus summarized by Senator Jones of Washington:

1. For the improvement of the navigation of rivers without cost to the government in connection with dams constructed for hydroelectric purposes in navigable streams.
2. For grants by the Secretary of War of authority to private parties for the construction and maintenance of such dams when navigation facilities can be improved thereby, such authority to extend for fifty years and until the property necessary for such a development is taken over and just compensation paid for it either by the government or a duly authorized new grantee.
3. For diligent construction, completion and operation of such dams, subject to market conditions.

4. For the construction by the grantee of suitable locks, without cost to the government, when required by the Secretary of War.

5. For payment to the government by the grantee of the cost of any investigation necessary to the issuing of the grant and the cost of such supervision of construction as may be necessary; and also the payment by the grantee of reasonable charges for benefits resulting from headwater improvements installed by the government and payment to the government of a reasonable price for the use of any public land taken.

6. For the regulation of the rates and service of the grantee by state authority, or, if the business is interstate, by the Interstate Commerce Commission, thereby assuring to consumers efficient service and fair, just and reasonable rates.

7. For reserving to the state authority over the waters and water powers subject to the paramount power of Congress over navigation, and for reserving also all the taxing powers of the states in relation to the properties.

8. For uniform accounting and examination of the books of grantees by the Secretary of War.

9. For leasing under similar conditions the right to utilize surplus water generated at dams constructed by the government.

Senators in charge of water-power legislation in the upper house also are expecting to have White House conferences, and it seems certain that the Administration bill will be introduced in the Senate or that its provisions will come before a Senate Committee in some form, so that when the House passes the Administration bill there may be a conference between the House and the Senate. This will give opportunity to compose the differences between the Administration bill, the Shields bill already passed by the Senate, and the provisions of any measure relating to the public lands which may come from the lands committee of the Senate.

Award of Medal at Annual Meeting of Mining & Metallurgical Society of America

The annual meeting of the Mining & Metallurgical Society of America was held at the Engineers' Club, New York City, on Jan. 8, 1917. At the afternoon session the following officers were elected: President, W. R. Ingalls; vice-president, J. Parke Channing; secretary-treasurer, L. D. Hunton; members of council, F. W. Bradley, J. V. N. Dorr, J. R. Finlay, Pope Yeatman, R. C. Gemmell.

Honorary membership in the Society was conferred on Dr. James Douglass and Prof. James F. Kemp.

The gold medal of the Society was awarded to Pope Yeatman for distinguished service in the administration of mines.

At the evening session there was some discussion of the surtax on professional incomes as imposed by the War Revenue Act, and a motion was passed declaring it to be the sense of the meeting that the surtax is inequitable and unjust. This action was communicated to the Engineering Council for such action as it might deem wise.

Following the transaction of business the Society listened to informal talks on conditions in Russia by J. P. Hutchins and F. W. Draper. Both of these engineers were able to speak from personal knowledge of events as observed during residence in Russia. Mr. Draper told the story of his experience in bringing from Russia to the United States over 20,000 oz. of platinum for the use of our Government, a task which he had only recently completed.

New Home of Dayton Engineers' Club

The Engineers' Club of Dayton, Ohio, comprising about 300 engineers in all fields of activity, has completed a handsome new club house at Monument Avenue and Jefferson Street, facing the river, and convenient to the center of the city. It is in keeping with the progressive spirit of the city, and is three stories high, facing 150 ft. on Monument Avenue and 125 ft.

NEW HOME OF DAYTON ENGINEERS' CLUB

on Jefferson St. The first floor has a ladies' room, billiard and game room, large main dining room, and small private dining rooms. On the second floor is a large auditorium, a library, and lounging room. On the third floor are bedrooms.

The club will be dedicated on Saturday afternoon and evening, Feb. 2. Invitations are being sent out throughout the Miami Valley. Col. E. A. Deeds, chief of the Aircraft Production Board, is president of the club, and Mr. C. F. Kettering vice-president.

Program of New York Meeting of A. I. M. E.

The 116th meeting of the American Institute of Mining Engineers will be held in New York from Monday, Feb. 18, to Thursday, Feb. 21 inclusive. The committee on arrangements consists of J. E. Johnson, Jr., chairman; Bradley Stoughton, vice-chairman; Ralph W. Deacon, J. V. N. Dorr, L. W. Francis, Mrs. S. J. Jennings, A. R. Ledoux, F. T. Rubidge, E. M. Shipp, G. D. Van Arsdale and A. L. Walker. The summarized program follows:

Monday, Feb. 18:

9 a. m. to 5 p. m., registration at Institute headquarters.

10 a. m. and 2 p. m., technical sessions.

12.30 p. m., luncheon at Engineering Societies' Building.

8.30 p. m., war smoker.

Tuesday, Feb. 19:

10 a. m. and 2 p. m., annual business meeting and technical sessions.

12.30 p. m., luncheon at Engineering Societies' Building.

8.30 p. m., announcement later.

Wednesday, Feb. 20:

10 a. m. and 2 p. m., technical sessions.

12.30 p. m., luncheon in Engineering Societies' Building.

7 p. m., "Hoover" dinner at Hotel Biltmore.

Thursday, Feb. 21:

All-day excursion to Princeton to visit aviation field.

An attractive program is being prepared for the ladies.

Licenses Required to Handle Ammonia Products

A proclamation has been issued by the President requiring the licensing of the importation, manufacture, storage and distribution of the following necessaries: Ammonia, ammoniacal liquors, and ammonium sulphate from whatever source produced. The proclamation continues as follows:

All persons, firms, corporations, and associations (except those specifically exempted by said act of Congress) engaged in the business of importing, manufacturing, storing or distributing ammonia, ammoniacal liquors, or ammonium sulphate from whatever source produced, are hereby required to secure a license on or before Jan. 21, 1918, which will be issued under such rules and regulations governing the conduct of the business as may be prescribed.

The Secretary of Agriculture shall supervise, direct, and carry into effect the provisions of said act.

Applications for licenses must be made to the law department, license division, United States Food Administration, Washington, D. C., upon forms prepared for that purpose.

Employees' Responsibility on Secret Processes

An interesting and important decision was recently handed down by the Supreme Court of the United States in the case of Walter E. Masland vs. E. I. du Pont de Nemours & Co. The former was formerly in the employ of the du Pont company and the company sought to restrain him from using or disclosing secret processes in artificial leather manufacture which it was claimed he had learned while in their employ. He claimed that the process was not secret and that he did not expect to use information gained in confidence. He was prevented by the court, however, from revealing to experts or other witnesses the data claimed as secret by the du Pont Company. The Circuit Court of Appeals reversed this decision however, but it was upheld by the Supreme Court. Their statement follows:

"The case has been considered as presenting a conflict between a right of property and a right to make a full defense, and it is said that if the disclosure is forbidden to one who denies that there is a trade secret, the merits of his defense are adjudged against him before he has a chance to be heard or to prove his case. We approach the question somewhat differently. The word property as applied to trade-marks and trade secrets is an unanalyzed expression of certain secondary consequences of the primary fact that the law makes some rudimentary requirements of good faith. Whether the plaintiffs have any valuable secret or not, the defendant knows the facts, whatever they are, through a special confidence that he accepted. The property may be denied, but the confidence cannot be. Therefore, the starting point for the present matter is not property or due process of law, but that the defendant stood in confidential relations with the plaintiffs, or one of them. These have given place to hostility, and the first thing to be made sure of is that the defendant shall not fraudulently abuse the trust reposed in him. It is the usual incident of confidential relations. If there is any disadvantage in the fact that he knew the plaintiffs' secrets, he must take the burden with the good.

"The injunctions asked by the plaintiffs forbade only the disclosure of processes claimed by them, including the disclosure to experts or witnesses produced during the taking of proofs—but excepting the defendant's counsel. Some broader and ambiguous words that crept into the decree, seemingly by mistake, may be taken as stricken out and left on one side. This injunction would not prevent the defendant from directing questions that should bring out whatever public facts were nearest to the alleged secrets. Indeed, it is hard to see why it does not leave the plaintiff's rights somwhat illusory. No very clear ground as yet has been shown for going farther. But the judge who tries the case will know the secrets, and if in his opinion and discretion it should be advisable and necessary to take in others, nothing will prevent his doing so. It will be understood that if, in the opinion of the trial judge, it is or should become necessary to reveal the secrets to others, it will rest in the judge's discretion to determine whether, to whom, and under what precautions, the revelations should be made."

Fifth National Foreign Trade Convention

The National Foreign Trade Council has called the Fifth National Foreign Trade Convention to meet at the Gibson Hotel, Cincinnati, on Thursday, Friday and Saturday, Feb. 7, 8, 9. The part of foreign trade in winning the war will be the theme of the convention.

All Americans engaged in, or desirous of entering overseas commerce, and especially all chambers of commerce, boards of trade, and other commercial and industrial organizations, as well as firms and individuals, are invited to take part, individually or by appointment of delegates, in this convention.

Approximately one-half of the time of the convention will be given to the presentation of prepared papers and reports dealing with one or another of the numerous phases of this great convention theme. The remainder will be devoted to group sessions for the intensive discussion of concrete problems, under the leadership of specially qualified experts. The departments of government dealing with foreign trade matters, including the War Trade Board, and other war organizations, will lend their hearty co-operation.

The offices of the council are at No. 1 Hanover Square, New York.

Technical Association of Pulp and Paper Industry

The annual meeting of the association will be held at the Waldorf-Astoria in New York on Tuesday, Wednesday and Thursday, Feb. 5, 6 and 7. The executive committee will meet on Tuesday and a general meeting will be held on Wednesday morning. On Wednesday afternoon separate sectional meetings will be held on "Acid Sulphite Manufacture and Problems Relating to Engine Sizing." The annual dinner will be held Wednesday evening.

Société de Chimie Industrielle

The New York Section of the Société de Chimie Industrielle will meet for organization immediately following the meeting of the British Society of Chemical Industry at the Chemists' Club, 50 East Forty-first Street, at 8.15 p. m., on Friday evening, Jan. 18. All those interested are earnestly requested to be present.

By-products from Garbage.—The Chicago Chemical Bulletin says that New York City's garbage, by treatment in a $3,000,000 recovery plant of the latest type (so-called Cobwell process, chemical) on Staten Island, yields the following commercial products: Grease for 70,000,000 cakes of soap, 1500 tons of nitrogen, 2000 tons of phosphoric acid, 500 tons of potash. The increased recoveries amount to 25 per cent more than under the best previous reduction methods used for New York's garbage.

Italian Leucitic Lavas as a Source of Potash

BY HENRY S. WASHINGTON

WITH the present urgent need of potash to replace that which was previously sent out from Germany, other sources of supply of this substance assume great importance. In recent publications of the United States Geological Survey, Phalen[1] and Gale[2] describe the different sources in considerable detail, though confining themselves chiefly to those in the United States. While some of these sources appear to be promising, at least under present conditions, others, even at maximum possible utilization, can furnish but a small fraction of what is needed.

The igneous rocks of the earth's crust contain, on an average, about 3 per cent of potash (K_2O), some of them running as high as over 10 per cent. It is upon these, and especially those richest in potash, that the world will ultimately have to depend in great part for its supply.[3] At the present time, it would seem, no satisfactory practicable method has yet been devised for the extraction of potash from these rocks on a large commercial scale which could compete successfully with the German potash deposits in normal times. The solution of this important problem must be left to the future, and the subject will not be considered here.[4] It will, however, not be amiss to call the attention of those interested in potash to what may justly be considered as the greatest accumulation of very highly potash-rich igneous rocks known to exist on the earth's surface—the leucitic lavas of the Italian volcanoes.

Well known as they are to geologists, it is somewhat surprising that little or no mention is made of these rocks by writers dealing with sources of potash. Phalen, Gale, and Pogue, in the papers already cited, when enumerating the silicates possibly capable of yielding commercial amounts of potash, discuss feldspar, sericite, glauconite, and the lavas of the Leucite Hills in Wyoming, but make no mention of those of Italy, presumably because they were dealing more especially with possible domestic sources of supply. The Italian lavas are briefly alluded to by Schultz and Cross[5] in a paper devoted to the Wyoming rocks. Both De Launay[6] and Lindgren[7] dismiss leucitic rocks from consideration as a practicable source of supply because of the difficulty of extraction. Both of these authors, however, were writing before the present highly abnormal conditions obtained.

In their own country the Italian lavas have received some attention. Monaco[8] has published several short papers describing the results of experiments in treating the rock powders with dilute solutions, in simulation of the action of soil fluids, a small amount of potash being extracted. Moderni,[9] prior to the outbreak of the war, published a paper in which he briefly describes the different Italian volcanoes that furnish leucitic rocks, with descriptions of the more important lava flows, and their possible utilization as a source of potash.

Leucitic Rocks

It would not be appropriate here to go into detailed, technical descriptions of the Italian leucitic rocks,[10] but it may be well to devote a few words to them, as the use of some technical terms is necessary in describing the volcanoes and their rocks.

The minerals which are especially important for their potash content in the Italian rocks are two in number, both silicates of potash and alumina, but with different ratios of silica to the other two oxides.

Leucite

The most important, because it is the richer in potash and the more abundant in these lavas, is leucite. Although met with in volcanic lavas in various localities in different parts of the world, leucite is rather a rare mineral, except along the line of the Italian volcanoes, where it may be said to be characteristic of the lavas. It is white or light grayish, with a dull luster, and almost invariably in well formed crystals which, though bounded by crystal faces, are spherical in general form. Theoretically leucite ($KAlSi_2O_6$) contains 21.5 per cent of potash (K_2O), with 23.5 of alumina (Al_2O_3) and 55 of silica (SiO_2), but analyses show that the natural crystals actually contain about 19.5 of potash, the smaller percentage being due to the presence of small amounts of soda and other impurities. The fresh mineral contains no water. Leucite is readily decomposed by acids, the potash and alumina going into solution, and the silica being left in granular form. The Italian leucite crystals vary much in size, from that of a tennis ball or larger, through sizes of a walnut or a pea (these being much more common), down to microscopic dimensions, so that often to the naked eye the rock does not appear to contain leucite. In places, especially among some of the incoherent tuffs, there are masses made up almost wholly of loose leucite crystals, generally of medium sizes.

Orthoclase

The other mineral, orthoclase (potash feldspar) is much less abundant and of less importance than leucite in most of the Italian leucitic lavas. Elsewhere, throughout the world, it is much the more abundant and important of the two. It is typically white, with a

[10] For complete, petrographic descriptions and analyses of the various types see H. S. Washington, The Roman Comagmatic Region, Publication No. 57, Carnegie Institution of Washington, 1906. Descriptions will also be found in most of the papers cited later in connection with each volcano.

vitreous luster, and cleaves readily in two directions. When crystallized the crystals very frequently have a tabular form. Theoretically pure orthoclase ($KAlSi_3O_8$) contains 16.9 per cent of potash, with 18.4 of alumina and 64.7 of silica. Actually, however, all the "orthoclase" of the Italian volcanoes (as well as nearly all of it elsewhere), contains varying, and sometimes large, amounts of soda feldspar (albite), so that the actual amount of potash present varies from less than 7 to about 10 per cent. In a very few Italian leucitic rocks the amount of orthoclase exceeds that of the leucite, but in the great majority it is much less, and in a large number of leucitic lavas it is wholly absent.

The chief minerals associated with these in the Italian lavas are soda-lime feldspars (silicates of alumina, soda and lime, of variable composition), and augite (silicates of iron, lime, magnesia, and a little alumina). In some of the lavas either or both of these may be present in amounts equal to that of the leucite. Other minerals occur as rock constituents in these lavas, such as olivine, nephelite, sodalite, magnetite, and apatite, but usually only in very minor amounts, so that, in general, they would not affect the percentage or the practical extraction of potash.

The leucitic rocks of which these minerals are the constituents must be described very succinctly. They may be broadly divided into three main groups, called respectively leucite trachytes, leucite tephrites, and leucitites.

LEUCITE TRACHYTES

The leucite trachytes are light gray and generally quite compact. They are composed essentially of sodic orthoclase and leucite, the former in some cases more abundant than the latter, with very subordinate amounts of soda-lime feldspar, augite, and other minerals. In these rocks the leucite crystals frequently attain large dimensions, while, in general, the orthoclase exists for the most part in microscopic size. As a class they are the richest in potash, averaging about 9.68 per cent K_2O, and some of them showing percentages of 10.40, 10.47, 10.49 and 10.63.

LEUCITE TEPHRITES

The leucite tephrites are dark gray to nearly black, and are usually compact. They are composed essentially of leucite, augite and soda-lime feldspar, with very small amounts of other minerals. Few of them show leucites visible to the naked eye, and then the crystals are small. As a usual thing leucite and augite each make up about 30 per cent of the rock, with the feldspar in somewhat less amount. Their potash content varies from about 7.50 to over 8 per cent, and they are much higher in lime, iron and soda, and lower in silica, than the preceding type.

LEUCITITES

The leucitites are dense, black, basaltic rocks, which scarcely ever show visible crystals of any sort. They are composed essentially only of leucite and augite, which constitute about 80 per cent or more, with very small amounts of other minerals. Their potash content is about that of the leucite tephrites, though slightly lower as a rule, and otherwise in chemical composition they much resemble these, but mineralogically and chemically the two types tend to grade into each other.

The average potash content of the Italian leucitic lavas, as shown by 27 complete chemical analyses made by me,[11] embracing representatives of all the types, is 8.72 per cent; while the average for all the lavas of these volcanoes, leucitic and non-leucitic, based on 44 analyses, and taking into account the relative abundance of the various kinds,[12] is 8.31 per cent. No other region of igneous rocks of commensurate, or even far greater, size is known that is so high in potash.

These leucitic lavas form flows that vary greatly in dimensions; up to 20 or more kilometers long and several kilometers broad, where not covered by tuffs, and as thick as 10 or more meters. In a general way it may be said that their exposed portions are from 1 to 5 kilometers in length, by about one or less in breadth, and with an average thickness of from 4 to 5 meters. They frequently show prismatic or platy parting, which facilitates extraction. Many of the flows are extensively quarried for paving blocks, which are commonly used in this part of Italy.

In addition to the lavas which carry leucite there are others at some of the volcanoes that are free from leucite, but contain large amounts of orthoclase or other feldspars. These are trachytes, andesites and basalts. The potash content of the trachytes (orthoclase lavas) varies from about 7.50 to over 9 per cent. The few andesites and basalts contain little potash. There are also very extensive beds of more or less incoherent tuffs, derived from the loose ashes and scorias thrown out by the volcanoes. While some of these are not leucitic, many of the them are quite rich in this mineral and contain very considerable percentages of potash.

Methods of Cubature

The method adopted by me for calculating the volumes of the volcanic masses was as follows: As they all have an approximately circular plan, with sides that slope up (more or less regularly) to a circular summit, the form was assumed to be that of a frustum of a cone. The irregularities of the sides, due to erosion or the presence of small, flank eruptions, were disregarded as of negligible magnitude for the rough calculations involved, and they tend more or less to balance each other. No correction was made for the natural concavity of the sides of a volcanic cone, as the error involved is small and is compensated by the lava flows that extend beyond the assumed base.

At the topographically highly irregular Bolsena and Bracciano volcanoes, the base selected was the sedimentary platform on which the volcanic mass rests; while at the more regular Vico, Alban Hills, Rocca Monfina and Vesuvius volcanoes it was assumed to be the lower border of the main cone, where it merges into the nearly horizontal lava flows and sheets of tuff that extend around it. This base would be somewhat above the sedimentary platform, and so the estimated volumes for the lavas of these cones are rather too small. The assumed top circle of the frustum varies with the form of the volcano. At Bolsena, Vico and Bracciano it was assumed to be that of the rim surrounding the central lake or crater, an average height above the base being

[11] H. S. Washington, The Roman Comagmatic Region, p. 146.
[12] H. S. Washington, The Roman Comagmatic Region, p. 174.

calculated for this, and the volume occupied by the central cavity being subtracted. At the Alban Hills, Rocca Monfina and Vesusvius, where, of the original early crater wall there remains only a semicircular ridge, the top is the approximately circular floor of the crater of the first eruptive period, inside the semicircular ridge. The volume of this ridge, together with that of the latest small, terminal cone (except at Rocca Monfina) is added to that of the main cone.

The formula used was that for a frustum of a cone:

$$V = \tfrac{1}{3}\pi h(a^2 + ab + b^2),$$

where h is the height from base to top, and a and b the radii of the base and top circles.

V. Sabatini[13] adopted a different method for the cubature of the Alban Hills and Vico, though, as his object was the calculation of the total existing material ejected; his bases are more extensive than mine, especially at the former volcano. The areas included by the successive 50-meter contour lines were measured with a planimeter, and the volumes of a series of annular cylinders were calculated, whose bases were these areas and whose heights were about the mean altitudes.

The Volcanoes

The Italian volcanoes[14] that are characterized by leucitic lavas are seven in number, forming a row that extends from Orvieto at the northwest to Naples at the southeast (a distance of about 300 kilometers), parallel to and quite near the west coast of the Italian peninsula. Vesuvius alone is active, the others having been long extinct, and some of them have largely lost their original forms through erosion.

Bolsena Volcano

The most northerly and the largest is that known as the Bolsena Volcano[15], which lies just west of Orvieto and some 90 kilometers northwest of Rome. It is the earliest in geological age of the seven, and is considered by some to be the remains of one huge volcano, while others consider it to be a complex of four moderate sized cones. Into this question we need not go. The total area covered by its volcanic rocks is about 2289 square kilometers.[16]

In the center is an elliptical lake, Lake Bolsena, 305 m. above sea level, with an area of about 115 square kilometers and a maximum depth of 146 meters. Surrounding this is a broad girdle of hills, made up of lavas and tuffs, with numerous, radiating erosion valleys and lava flows, extending to the borders of the area. The slope, in general, is upward from the borders of the mass toward the hills encircling the lake (these having an average altitude of about 300 meters above its level). But the topography is distinctly irregular and largely determined in details by the erosion of the various cones that compose the group. The diameter of the almost circular igneous area is about 40 kilometers, and the average altitude of the sedimentary base, though somewhat variable, may be taken as about 230 meters above sea level.

Apart from a few flows of non-leucitic rocks (andesites and trachytes), which cannot make up 10 per cent of the lavas, the rocks are highly leucitic lavas and their tuffs. Incidentally, it may be mentioned that the lavas of the Bolsena Volcano are more varied than those of almost any of the other volcanoes along the line. From the specimens collected by myself, and from the descriptions by others, though a complete study has not yet been made, it would appear that, of the lavas, leucite tephrites are somewhat the most abundant, leucite trachytes almost as much so, and leucitites in less amount. It would also appear that leucite trachytes predominate in the northwestern sector of the area, leucite tephrites northeast and southwest of the lake, and leucitites to the southeast.

So far as I am aware, no attempt has been made to calculate the volume of the Bolsena Volcano or of its lava flows—a problem which, indeed, can only be solved in a very rough way, because of the irregular topography. The result will, at least, give the order of magnitude and a rough approximation of the volumes involved. From the data furnished by the excellent Italian topographic maps, some of which have been given above, we obtain a total volume for the present volcanic mass of 178.9 cubic kilometers. Deducting from this the volume occupied by the lake and its basin, 46.2 cubic kilometers, there remains a volume of about 133 cubic kilometers of igneous rocks (lavas and tuffs) now existing above the sedimentary platform of the volcano. It is difficult to estimate the relative amounts of lavas and tuffs, but from my observations in the field it would seem to be reasonable to consider that the lavas form one-tenth of the mass. Of these lavas we may very liberally allow one-tenth for those which are non-leucitic. We thus obtain a final result of about 12 cubic kilometers of leucitic lavas, an estimate that may be considered to be conservative. Assuming that the average specific gravity of the rocks is 2.8, and that the potash content is about 8 per cent, this being based on a number of good analyses and study of my specimens, we arrive at a final total of 2,688,000,000 metric tons of potash (K_2O) contained in the leucitic lavas of the Bolsena Volcano.

Vico Volcano

This volcano[17] lies a few kilometers to the southeast of the Bolsena Volcano, 65 kilometers northwest of Rome, the city of Viterbo being at its north foot. It is one of a pair of volcanoes, but as the other, Monte Cimino, has poured out no leucitic lavas, this will not be considered here.

The Vico Volcano forms a quite regular cone, much better preserved and simpler than Bolsena. The cone proper has a circular base, at an altitude (average) of about 330 meters above sea level, and with an area of about 350 square kilometers, though extensive, thin beds of tuff extend beyond this. In the center is a nearly circular crater pit, about 9 kilometers in diam-

[13] V. Sabatini, Vulcano Laziale, p. 134; Vulcani Cimini, p. 269.

[14] It may be pertinent to mention that my knowledge of these volcanoes and their lavas is the result of studies in the field and in the laboratory extending over many years.

[15] H. S. Washington, Italian Petrological Sketches, Jour. Geol., IV, pp. 541-566, 1896; P. Moderni, Studio Geologico dei Vulcani Vulsini, Bolletino Comitato Geologico, 1904, 234 pp., with topographic map 1:100,000. It is to be noted that references to only two or three of the most descriptive papers are given in the case of each volcano, as the literature is far too extensive for full citation here.

[16] In this paper all measurements are given in the metric system, as this is the official system of Italy and all the maps on which the calculations are based are in accordance with it. It will be useful to note the following approximate equivalents.

1 meter	=	39.37 in. or 3.28 ft.
1 kilometer	=	0.62 mile
1 square kilometer	=	0.39 square mile
1 cubic kilometer	=	0.24 cubic mile
1 metric ton	=	2,205 lb. = 1.1 short ton

[17] H. S. Washington, Italian Petrological Sketches, Jour. Geol., IV, p. 826, 1896; V. Sabatini, Vulcani Cimini, Mem. Carta Geol. Ital., XV, 1912. Geological map, 1:75,000.

eter and 275 meters deep. The ridge surrounding the crater is rather sharp and has an average height above the base of about 450 meters. On the crater floor is a small, solid cone, Monte Venere, which is 320 meters high, near the foot of which is a small, shallow lake.

The lavas of Vico are much more uniform than those of Bolsena. There is a small proportion, less than 10 per cent, of trachytic rocks which, though they contain orthoclase instead of leucite, carry about 9 per cent of potash. Of the other lavas the greater part are leucite trachytes (often with abundant and large leucite crystals), and less leucite tephrites, while leucitites seem to be absent. In potash content the lavas range from 10.47 to 7.47 per cent, with an average of about 9.25.

Because of the fair state of preservation of the originally quite regular cone, the calculation of the volume of this volcano is simpler and susceptible of more accuracy than that of Bolsena. It has already been carried out by Sabatini, whose results will be given presently. Using the data given above, we obtain a total volume for the cone above the sedimentary platform of 83.4 cubic kilometers, to which is to be added 0.6 for the mass of Monte Venere, making a total of 84. From this is to be subtracted the volume of the crater, about 3.5 cubic kilometers, leaving a final volume of volcanic rock of 80.5 cubic kilometers. Assuming, as before, that the lava-flows form about one-tenth of the mass, the average specific gravity as 2.8 and the average potash as 9 per cent, we get a total potash content of 1,668,600,000 metric tons.

Using a somewhat different method, Sabatini[18] obtains a total volume of igneous material above the sedimentary base of 96.3 for both Monte Vico and Monte Cimino. Of these combined masses, according to his figures, Monte Vico makes up 84 per cent, so that his estimate for the Vico Volcano alone would be 80.6 cubic kilometers, a figure in very good agreement with that obtained by me independently, 80.5, using a different method.

BRACCIANO VOLCANO

This volcanic area[19] lies south of the preceding one, and about 25 kilometers northwest of Rome. The igneous rocks cover an area of about 1300 square kilometers, and the topography in its general features resembles that of the Bolsena Volcano, but on a somewhat smaller scale. There is a central lake, Lake Bracciano (area 57.5 square kilometers), the circle of hills about it being highest, 440 meters above the lake, on the northwest, and lowest on the south. It would appear that the mass is a complex of small cones, possibly parasitic to a large central one; but erosion has so altered the original forms that decision is difficult. Thus, the topography of the area is very irregular, though in a general way the surface slopes upward toward the hills bordering the lake.

The lavas of this volcano are predominantly leucite tephrites and leucitites, with very few leucite trachytes in the northwestern sector, and a few occurrences of non-leucitic trachytic rocks. Few good analyses of the lavas of this volcano have been made, but these indicate that they have an average potash content of about 9 per cent. One of the leucite trachytes contains 10.49 per cent.

Because of the highly irregular topography any satisfactory or approximately exact calculation of the volume of the igneous mass, and especially of that of the leucitic lavas, is very difficult. I have attempted it in a rough way, using the data of the Italian topographic maps, with the following results, which must be regarded as only a very rough approximation. The total volume of the volcano is about 48 cubic kilometers, from which is to be subtracted the volume of the lake basin (11 cubic kilometers), leaving for the volume of the igneous rocks 37 cubic kilometers. Assuming that the leucitic lavas constitute 10 per cent of this, with a specific gravity of 2.8, and 9 per cent of potash, they would contain 932,400,000 metric tons of K_2O.

ALBAN HILLS

This volcano[20], also called the Latian Volcano, lies about 13 kilometers southeast of Rome. It forms an isolated conical mass, with the original volcano form fairly well preserved. From a very extensive, very gently sloping base of tuffs, with some long lava flows, the cone proper (having an area at its base of about 345 square kilometers), rises to a circular ridge, with elevations of from 550 to 940 meters above sea level. This incloses the old crater floor, about 10 kilometers in diameter and with an elevation that may be placed at about the 600-meter contour line, the sedimentary base being assumed to be at about 200 meters. In the center rises a small, terminal cone, with the remains of a crater. Several small crater lakes, due to side eruptions, are found on the flanks of the main cone.

The lavas of this volcano are remarkably uniform, leucitites being overwhelmingly predominant, with very rare leucite tephrites. There are no leucite trachytes, or trachytic or andesitic rocks. Tuffs are abundant, but they, especially those that make up the cone proper, are mostly leucitic. Good analyses of these lavas are not numerous, but they indicate that the average potash content is somewhat over 8 per cent.

The cubature of this volcano has been carried out by Sabatini, whose results will be given below. Using the data given above and others derived from study of the map, I obtained the volume for the main cone, above the 200-meter contour line (which is approximately that of the encircling railroads or the lower limit of the area of leucitic tuffs given on Sabatini's map), of 78.5 cubic kilometers. Adding to this the volumes of the small cone, 2 cubic kilometers, and that of the ridge, 2.5 cubic kilometers, we get a total volume of about 83 cubic kilometers. Assuming, as before, that the lavas constitute one-tenth of this, have an average specific gravity of 2.8, with an average potash content of 8 per cent, they would contain some 1,859,200,000 tons of K_2O.

Sabatini,[21] using the method outlined above, obtained results which, though differing somewhat from mine, are fairly concordant, considering the differences in method. His area at the altitude of 174 meters (the nearest taken by him to my base altitude of 200), is 327 square kilometers, my figure, on the assumption that the base is circular, being 345. The volume of the cone from this 174-meter base to the altitude of 608

meters is 93 cubic kilometers, my result from the 200 to the 600-meter levels being 78.5.

HERNICAN VOLCANOES

In the valley of the Sacco River, about 65 kilometers southeast of Rome (the country of the ancient Hernici), are the remains of about eight small volcanic cones.[22] These are composed almost entirely of leucite tephrites and their tuffs, the lavas containing about 8 per cent of potash. They might contain in all something like 100,000,000 tons of potash; but the amount is so small and their distance from industrial centers is so great that they need not be considered in the present connection.

ROCCA MONFINA VOLCANO

This volcano[23] lies about 50 kilometers north of Naples, between the Garigliano and Volturno Rivers. Its igneous rocks cover an area of about 225 square kilometers. In general structure this volcanic mass much resembles Vico, the Alban Hills and Vesuvius, though it is not quite as well preserved. There is a large main cone, surmounted by a semcircular ridge, which reaches on the west a height of 926 meters above the sea, the original ridge being worn down to a series of low hills on the east. The original circular crater floor, something like 400 meters above the base,[24] has a diameter of about 6 kilometers. From the center of this rises a small cone, Monte Santa Croce, of non-leucitic andesite.

The lavas of this volcano are almost as varied in their characters as those of Bolsena. There are some flows of non-leucitic lavas (basalts, andesites, trachytes), but the leucitic lavas preponderate very greatly, and would seem to be rather more abundant relatively to the tuffs than in the other volcanoes. All three kinds are found, leucite tephrites being the most abundant, with leucitites and leucite trachytes probably in the order named. The last are especially noteworthy, as are some of the tuffs, for the abundance of very large leucite crystals. There are but few satisfactory analyses of the lavas of this volcano, but a conservative estimate would place the average potash content at at least 9 per cent. One leucite trachyte contains 10.64 per cent, the highest figure for potash obtained in the Italian lavas.

In the absence of adequate topographic data, the cubature of this volcano must be regarded as but roughly approximate. It is estimated that the cone, from the base to the crater floor, has a volume of about 40.5 cubic kilometers, to which is to be added the volume of the semicircular ridge, approximately 2.5, making a total of 43 cubic kilometers. Assuming that the lavas are at least one-tenth of this, and the non-leucitic flows[25] one-tenth of the lavas, there is left a volume of about 4 cubic kilometers of leucitic lava flows. With an average specific gravity of 2.8, and a potash content of 9 per cent, these would contain 1,008,000,000 tons of K_2O, a figure which, by comparison with the analogous volcanoes of Vico and the Alban Hills, I consider to be much below the true one.

VESUVIUS

This, the only active volcano of the series,[26] lying some 10 kilometers east of Naples, is so well known that it calls for little description. Leaving out of account the extensive beds of tuff that cover the surrounding Campagna, the area of the base[27] of the cone is about 80 square kilometers, the average altitude of the boundary being about 150 meters above the sea. The cone slopes quite regularly up to the Pedimentina, a circular plateau at an altitude of 600 to 800 meters. This is bounded on the north by the narrow semicircular ridge of Monte Somma, which rises to a maximum height of 1132 meters above sea level. Near the center of the Pedimentina is the modern cone, about 2 kilometers across at its base and 400 meters high. The present crater at the summit of this cone is about 1000 meters in diameter and 320 meters deep.

On the whole, the lavas of Vesuvius are very uniform and are all leucitic. With the exception of some of the flows of Somma and a few early beds of pumice, they may be referred to the leucite tephrites with scarcely an exception. Judging from observations on the inner walls of Somma and of the active crater, lava-flows and dikes are quite abundant as compared with the tuffs and ashes. The average potash content of the Vesuvius lavas is between 7.50 and 8.00 per cent.

Well known and much studied as is Vesuvius, it is rather remarkable that no attempt appears in its literature to calculate its volume. Using the data given above, supplemented by study of the topographic map, it is estimated that the main cone, from the base of 150 meters to the Pedimentina, has a volume of 20 cubic kilometers. To this must be added the volume of the Somma ridge above the Atrio level, 0.5, and that of the modern cone, 0.7 cubic kilometers, making in all a total of at least 21 cubic kilometers. Considering the relative abundance of the lava flows and dikes, and the fact that most of the ashes and scorias are high in potash, it would seem reasonable to assume that the lavas make up about one-seventh of the mass. On this basis, and with an average specific gravity of 2.8, and potash content of 7.5 per cent, we obtain 8,400,000,000 tons of leucitic lava, containing 630,000,000 tons of potash.

Immediately west of Naples is a volcanic district, the Phlegrean Fields, which covers about 150 square kilometers, and in which are found about twenty-six small cones. These are mostly of non-leucitic tuffs, with some lava flows, all of them non-leucitic orthoclase trachytes. They average about 8 per cent in potash content.

RECAPITULATION

For convenience the various data set forth in the preceding pages are here tabulated:

[27] The boundary of this is approximately the highway that encircles Vesuvius, passing through Pollena, Somma, Ottaiano, Avini, Bosco Tre Case, and the railroad just above Torre del Greco and Portici

SUMMARY OF DATA AS TO POTASH IN LEUCITIC LAVAS OF ITALIAN VOLCANOES

Volcano	Area of Base Km²	Alt. of Base* Met	Average Height Main Cone†	Total Volume‡ Volcano Km³	Leucitic Lavas Metric Tons	Per Cent K_2O	Amount of Potash Metric Tons
Bolsena	2289	230	350	133	33,600,000,000	8	2,688,000,000
Vico	350	330	450	80 5	18,540,000,000	9	1,668,600,000
Bracciano	1300	220	200	37	10,360,000,000	9	932,400,000
Alban Hills	345	200	400	83	23,240,000,000	8	1,859,200,000
Rocca Monfina	225	200	400	43	11,200,000,000	9	1,008,000,000
Vesuvius	80	150	550	21	8,400,000,000	7.5	630,000,000
Total	...	....	.....	.....	105,340,000,000	....	8,786,200,000

*Above sea-level. †Above base. ‡Corrected for crater, etc.

In considering these figures it must be borne in mind that in nearly, if not quite, all respects they are thought to be under, rather than over, estimates. This, on the following grounds. The dimensions and volumes of the calculated volcanic masses are those of the main cones, and, except in the cases of Bolsena and Bracciano, disregard portions of flows extending beyond the limits of the bases selected. The assigned altitude of the base above sea-level has been liberally high, and the average height of the cone above it is regarded as, in general, rather under than above the truth. The choice of figures for specific gravity and potash percentage have also been moderate. It is thought that the only factor that may be possibly too high is the assumption that the lavas constitute one-tenth of the volcanic mass. This, however, is based on rather extensive observations in the field, as well as on consideration of the fact that in the mass of the main cone, which alone has been considered in the preceding calculations, the relative amount of lava to tuffs and scoria is always very much greater than in the outlying or surficial portions of the volcano. This is well seen in the walls of Somma, the crater of Vesuvius, the walls of Val del Bove at Etna, in the crater of this volcano, and elsewhere. Even if somewhat high, it is to a certain extent compensated by the disregarding of the tuffs and scorias in the calculations, though many of these contain large percentages of potash. It would, therefore, be reasonable to suppose that the row of Italian volcanoes contains at least some 10,000,000,000 tons of potash (K_2O). It may be of interest to remark that the average annual consumption of potash in the United States for the ten years from 1905 to 1914 was almost exactly 200,000 short tons,[28] so that these volcanoes represent, "on paper," a 50,000 years' supply.

Practical Considerations

As was stated at the beginning of this paper, possible methods for the extraction of the potash from these rocks fall outside of the scope of this study and so will not be discussed here. It may be well, however, to point out very briefly some of the local features that may have a practical bearing.

All the volcanoes lie close to main, and in some cases also to subsidiary, railroad lines now in operation, and all, with the exception of Bolsena, near or not very far, from, large cities, either Rome or Naples.

As to power, although Italy is lacking in true coal, yet there is a very considerable amount of water power. Some of this has been utilized in late years in Lombardy and Piedmont, and there must be a noteworthy supply available in the streams that flow down the west slopes of the Appennines, though, not being a hydraulic engineer, I am not competent to discuss the subject. It may be mentioned that Moderni[29] calls attention to the fact that, at the Bolsena Volcano the Paglia River, which flows around its northern border, can furnish up to 260 hp., while the Marta, that drains the lake at the southeast, would yield up to 753 hp.

Although these volcanoes are surrounded by towns and villages, yet the main slopes of most of them, except the Alban Hills, are for the most part neither well populated nor highly cultivated. This is especially true of the Bolsena, Vico, Bracciano and Rocca Monfina volcanoes. At present there are very numerous, one might well say almost innumerable, lava-flows, varying in dimensions from 2 to 10 or more meters thick and up to 20 or 30 kilometers long, that are readily workable. Indeed, according to Moderni (page 10 of the paper just cited), leucite and leucitic lavas were extracted from the Alban Hills "for industrial purposes" (i. e., not for paving, but presumably for fertilizer uses) to the total amount of 22,300 tons in the years from 1903 to 1909, inclusive. Many quarries have been opened at several of the volcanoes, notably Bolsena, Alban Hills and Vesuvius, for the extraction of paving stones and their refuse, as pointed out by Moderni, would serve as a source of immediate supply of considerable magnitude.

In this connection it may be of interest to note that, according to Moderni, German industrial societies had in recent years, before the war, been active in researches in the Italian leucitic lavas for the manufacture of "chemical products."

Comparison with Other Regions

Although occurrences of leucitic lavas are scattered rather sporadically over the earth's surface, they are actually very rare rocks, and no other region is as yet known that is so extensive or so rich in them as that of the Italian volcanoes.

The occurrence that first calls for consideration is the very frequently mentioned district of the Leucite Hills, in Wyoming.[30]

A few other localities where leucitic rocks occur in the United States are known, as in Montana, the Yellowstone Park, Arkansas and New Jersey, but these can be of no commercial importance. The lavas of the Leucite Hills are highly potassic, averaging 10 per cent, and in this respect they slightly surpass those of the Italian volcanoes, whose average is nearly 9 per cent. As regards area, volume and amount of potash present, however, they are relatively insignificant. As calculated by Schultz and Cross (p. 35), the total tonnage of the leucitic rocks, including at some of the stocks the rock masses down to a depth of 3000 feet,[31] is 1,973,496,177 short tons, or about 1,794,100,000 metric tons of rock, containing 179,410,000 metric tons of potash. This is about one-fiftieth of the estimate of the potash contained in the Italian lavas, which we have reason to believe to be below the truth. In the one case it is a matter of acres, of area and feet of height, in the other

[28] See H. S. Gale, U. S. Geol. Surv., Min. Res., 1916, Pt. II, p. 76, 1917.

[29] P. Moderni, L'Industria Chimica, etc., I, p. 23, 1914.

[30] For a description of this as a source of potash see Schultz and Cross, Potash-bearing Rocks of the Leucite Hills, U. S. Geol. Surv., Bulletin 512, 1912. A full bibliography is given.

[31] Disregarding these, the lavas above the surface amount to about 1,627,819,000 short tons.

square kilometers of area and tens of meters of height of lava-flows.

Another silicate source of supply of potash in the United States (though not an igneous rock), is that of the beds of glauconite or greensand marl, of Upper Cretaceous and Eocene age, that extend in a narrow belt from near Sandy Hook, N. J., to beyond, Richmond, Va.[2] Clauconite is essentially a hydrous silicate of iron and potassium. The portions of the deposits that lie in New Jersey are the richest in potash, and a content of 6 per cent in the air-dry material would be a fair estimate for them. In New Jersey the belt is 160 kilometers long, with an average width of 16 kilometers. Assuming an average thickness of 6 meters (about 20 feet) for the glauconite beds, and the above percentage of potash, these New Jersey deposits would contain about 2,034,000,000 metric tons of potash, or about one-quarter or one-fifth of that contained in the Italian volcanoes. It would therefore appear that these glauconite beds of the Eastern States rank next to the Italian volcanoes in total amount of potash. The ease of extraction of the raw material and their proximity to facilities for treatment and transportation would seem to promise them to be of great value.

[2]See Lewis and Kümmel, Geol. Sur. of N. J., Bull. 14, p. 135, 1915; G. H. Ashley, U. S. Geol. Sur., Bull. 660-B, p. 27, 1917.

Among other localities where leucitic lavas occur in considerable amount may be mentioned the islands of Java, Celebes and Baween in the East Indies, New South Wales, the Eifel and Baden in Germany, Bohemia, Kamerun and East Africa and the Antarctic. But none of these, with the possible exception of the East Indies lavas, would seem to be sufficiently abundant or with a high enough average potash content to give promise of a commercial source of supply.

SUMMARY

Attention is called, as a future possible source of potash, to the leucitic lavas of seven volcanoes along the west coast of Italy, from Bolsena to Vesuvius. The rock types are characterized and the several volcanoes described very succinctly. The volumes of the volcanoes, the tonnage of the lavas, the percentage of potash and the total (minimum) amount of potash at each, are calculated. It is shown that the leucitic lavas of these volcanoes, with an average potash content of about 9 per cent, contain at least 8,786,200,000 metric tons of K_2O, making them the greatest accumulation of highly potash-rich silicate rocks known. Methods of extraction of the potash are not discussed.

The Effect of Addition Agents in Flotation—II

BY M. H. THORNBERRY AND H. T. MANN

As in the preceding discussion[1] of the effect of addition agents in flotation, the results obtained by the addition of various hydroxides are shown graphically in Charts 4, 5 and 6. The numerals on the charts are the numbers of the various experiments, three being made without any additions and four with each of the different agents. Those without addition agents are numbered 1, 2, 3 and 0, the last showing the average results of the first three. The numbers of experiments with addition agents are given in the following paragraphs, four to each experiment, and indicate results obtained respectively with 5, 15, 25 and 50 cc. of each agent.

To save repetition in the discussion of the results we shall refer in this article to Cleveland Cliffs Iron Company's flotation oil No. 1 as "oil No. 1," and to General Naval Stores flotation oil No. 17 as "oil No. 17."

The reader should also bear in mind that when statements are made that a certain reagent raised or lowered the grade of concentrate or extraction those results are compared with the results obtained when oil was used without any reagent.

HYDROXIDES

$(NH_4)OH$. Nos. 4 to 7

Ammonium hydroxides, when used with both oil No. 17 and cresylic acid, produced very similar results. The relative extraction was lowered about 7 per cent, while the grade of concentrate produced was only about 3 per cent low. With oil No. 1 both the extraction and grade of concentrate were lowered about 12 per cent.

NaOH. Nos. 8 to 11

When sodium hydroxide was used the results were so nearly like those of ammonium hydroxide that further discussion is unnecessary.

KOH. Nos. 12 to 15

Potassium hydroxide, when used with oils No. 1 and No. 17, lowered the extraction about 4 per cent, while the grade of concentrate produced was lowered about 6 per cent. Observations and results indicate that there is a possible relation between the flocculating effect of this salt and its effect on flotation results. However, it will take many more determinations to demonstrate the correctness or fallacy of this apparent relation. When this salt was used with cresylic acid the results checked more closely. The average extractions were lowered about 5 per cent, while the average grade of the concentrates was raised 2 per cent.

$Ba(OH)_2$. Nos. 16 to 19

With oil No. 1 barium hydroxide lowered the extraction about 15 per cent, and also lowered the grade of concentrate about 10 per cent. With oil No. 17 the extraction was lowered 7 per cent, while the grade of concentrate was lowered 4 per cent. With cresylic acid the extraction and grade of concentrate were lowered 9 per cent.

$Ca(OH)_2$. Nos. 20 to 23

Calcium hydroxide, when used with oil No. 1, gave extractions which varied from 2 per cent high to 5 per

[1]This Journal, Dec. 15, 1917, p. 709.

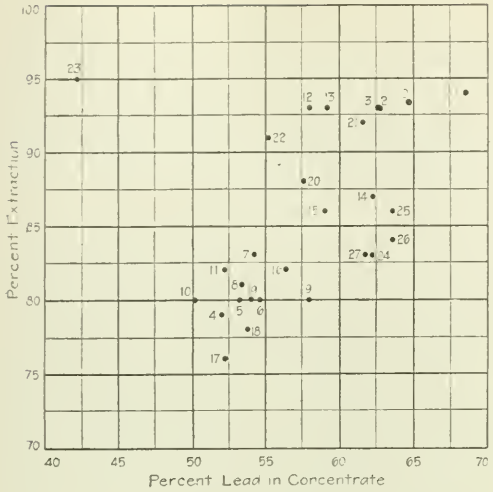

CHART 4—EFFECT OF HYDROXIDES ON FLOTATION OF GALENA WITH OIL NO. 1

cent low, while the lead tenor of the concentrate varied from 2 per cent low to 22 per cent low. With oil No. 17 the extraction varied from 4 per cent low to 10 per cent low, and the grade of concentrate varied from 2 per cent to 22 per cent low. With cresylic acid the extraction varied from 3 per cent high to about 8 per cent low, and the grade of concentrate varied from 2 per cent high to 6 per cent low.

Calcium hydroxide is practically the only hydroxide which exerted a pronounced effect on the character of the froth formed. With oil No. 1, 5 cc. of this salt gave a very wet froth composed of very small bubbles, which formed slowly and broke down very quickly. With 15 cc. the froth was wet, and composed of small bubbles which broke down slowly. With 25 cc. the froth was dry, and composed of large bubbles which formed quickly. With 50 cc. the froth was very dry, and composed of extremely large bubbles. This froth formed quickly and seemed to carry large quantities of gangue, and broke with difficulty. The froths with oil No. 17 were similar to those formed when oil No. 1 was used. With cresylic acid, 5 cc. of calcium hydroxide gave a wet froth composed of small bubbles which broke very quickly. The froth with 15 cc. was dry. When 25 cc. was used no froth was obtained when the usual quantity of oil—0.5 lb. per ton—was added. To complete the experiment another portion of oil equivalent to 0.250 lb. per ton was added. This extra addition of oil produced a froth composed of large bubbles which broke very quickly. With 50 cc. of this salt it was necessary to double the amount of oil before the tests could be completed. The froth formed when 1 lb. per ton of oil was added was extremely dry and composed of very large bubbles.

The relation between the flocculating effect of this salt and its effect on flotation deserves more work than we can devote to it at the present time.

The character of all froths formed was compared to the froths formed by the oil when no addition agent was present.

$Mg(OH)_2$. Nos. 24 to 27

Magnesium hydroxide, when used with any one of the three oils, lowered the extraction about 10 per cent, and had very little effect on the grades of concentrates produced. This salt modified the froths formed to such a little extent that no further discussion is necessary.

Summary of Effect of Hydroxides

The limited number of hydroxides tested, when considered as a group, produce results which are very similar to the results obtained when sulphates are present. The relative extraction is practically the same, but the grade of concentrates produced is slightly lower than when sulphates are present.

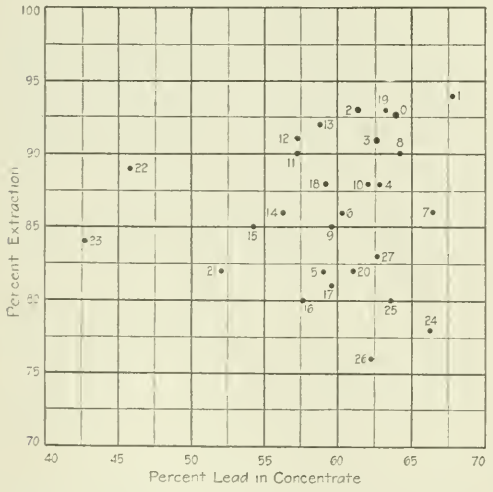

CHART 5—EFFECT OF HYDROXIDES ON FLOTATION OF GALENA WITH OIL NO. 17

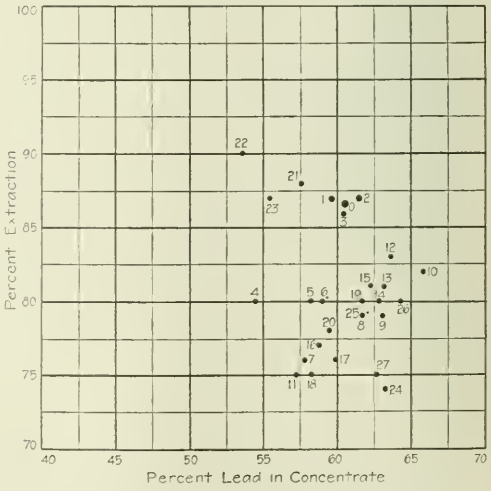

CHART 6—EFFECT OF HYDROXIDES ON FLOTATION OF GALENA WITH CRESYLIC ACID

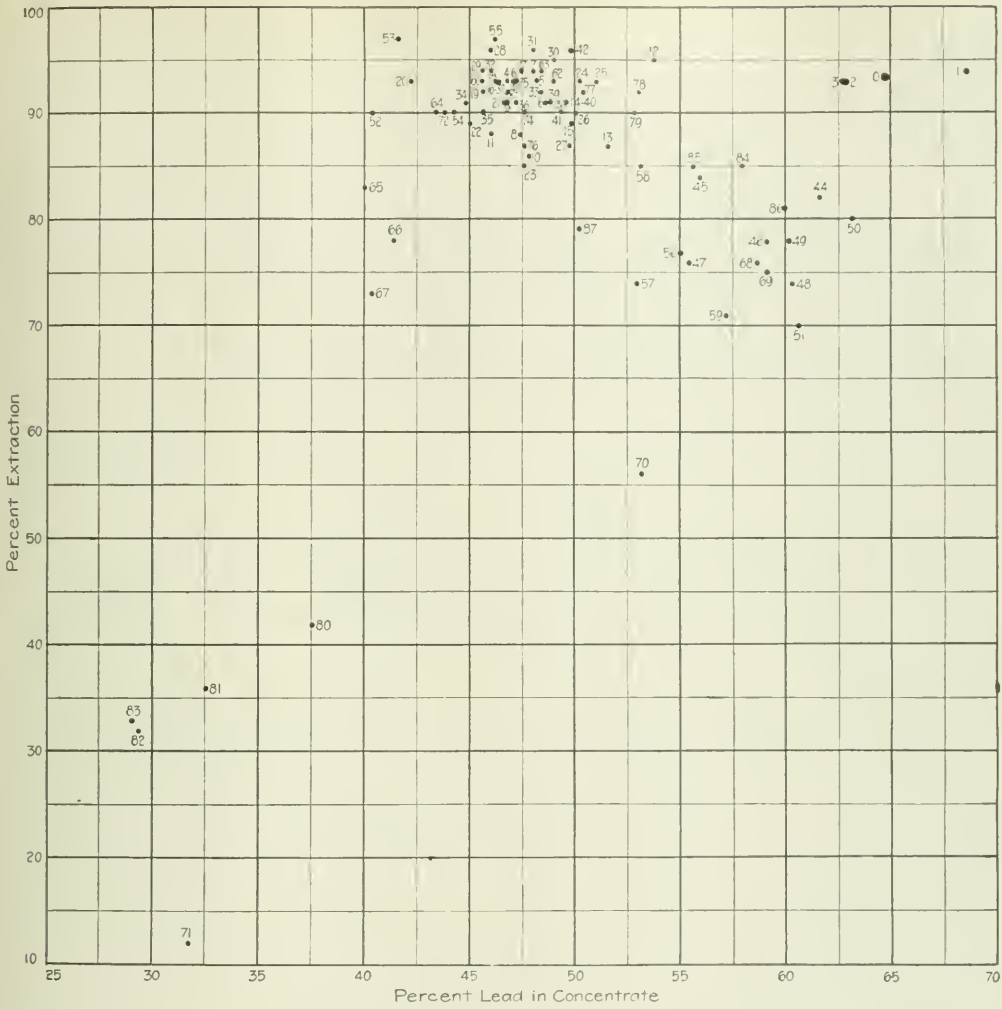

CHART 7—EFFECT OF NITRATES ON FLOTATION OF GALENA WITH OIL NO. 1

Nitrates

The results of these experiments are set forth in Charts 7, 8 and 9. Attention is here directed to the first three paragraphs of this article for an explanation of the significance of the numbers and their interpretation.

Nitric acid and many of the commoner nitrates when used in flotation tend to produce such an abundance of froth that it was found impractical to add the total amount of oil—0.5 lb. per ton—at the beginning of the test. When the total amount of oil was added at one time the entire amount of froth produced was evolved so quickly that an excessive overflow carrying large quantities of gangue was obtained, thereby necessitating the discarding of the test. To overcome this difficulty, the method of handling the nitrates was modified in the following manner: The desired quantity of the reagent having been added to the charge, oil was added at intervals in quantities equivalent to 0.125 lb. per ton. After each addition of oil the violent frothing was allowed to subside before another portion of oil was added. This procedure was continued until the total amount of oil—0.5 lb. per ton—had been added and the test was then completed, as described in the method for sulphates.

This tendency of quickly producing a very copious froth was so pronounced with nitric acid that it was found impossible to complete an experiment in which acid had been used. After twelve of fifteen trials with the acid, its use was abandoned.

The character and quantity of froth obtained when the nitrates were used varied widely. Small quantities of one reagent produced a froth composed of large bubbles, while larger quantities of the same reagent produced a froth of small bubbles. This condition was reversed with some of the other reagents. Repeated

tests, however, with the same addition agent under uniform operating conditions maintained in this work, always gave a froth having the same characteristics as mentioned above.

Many of the tests were completed in from 25 to 30 minutes, but were continued the full 40 minutes in order to keep operating conditions as uniform as possible.

Alkali Metal Nitrates

$NaNO_3$. Nos. 4 to 7.

Sodium nitrate had practically no effect on the extraction when used with oils No. 1 and No. 17, but when used with cresylic acid the extraction is noticeably lowered. The effect on the grade of concentrate produced was just the opposite. The grade of concentrate with oil No. 1 was lowered about 16 per cent; with oil No. 17 it was lowered about 8 per cent, while with cresylic acid the concentrate was of about the same grade as that produced when no reagent was present.

With oils No. 1 and No. 17 this salt gave a slow forming froth, which was composed of small, wet bubbles, which broke up slowly. With cresylic acid, sodium nitrate gave a dry, ephemeral froth, and the maximum extraction was obtained in 25 minutes.

KNO_3. Nos. 8 to 11.

Potassium nitrate, when used with oil No. 1 and cresylic acid, lowered the extraction more than the corresponding sodium salt. With oil No. 17 it had practically no effect on the extraction. The lead tenor of the concentrate varied with the oil used, being slightly higher with cresylic acid and about 14 per cent lower with oils No. 1 and No. 17.

With oils No. 1 and No. 17 the addition of 5 cc. of potassium nitrate solution produced a froth consisting of large, wet bubbles. When larger quantities were used the froth consisted of small, wet bubbles. With cresylic acid the froth formed slowly and consisted of large, dry bubbles, which broke quickly.

CHART 8—EFFECT OF NITRATES ON FLOTATION OF GALENA WITH OIL NO. 17

$(NH_4)NO_3$.
Nos. 12 to 15.

Ammonium nitrate lowered the extraction slightly when used with oils No. 1 and No. 17, and considerably when used with cresylic acid. It had practically no effect on the grade of concentrate produced when used with oil No. 17, and cresylic acid, but with oil No. 1 it lowered the grade of concentrate about 12 per cent.

This reagent, when used with oils No. 1 and No. 17, gave a very wet froth, composed of small bubbles which broke quickly. With cresylic acid the froth was not so wet, and the concentration was completed in 25 to 30 minutes.

$LiNO_3$.
Nos. 16 to 19

Lithium nitrate had little or no effect on the extraction. The lead content of the concentrate produced was about 16 per cent lower with oil No. 1,

12 per cent lower with oil No. 17, and 3 per cent higher with cresylic acid.

The froth formed when this salt was used varied with each oil. Oil No. 1 gave a wet froth, composed of medium-sized bubbles; oil No. 17 gave a froth similar to oil No. 1, except that the bubbles were much smaller. Cresylic acid gave a dry, ephemeral froth, composed of medium-sized bubbles, and the concentration was completed in about 25 minutes.

The alkali metal nitrates tested gave very similar results, the general tendency being to lower slightly the extraction. The effect on the grade of concentrate produced seemed to depend more on the oil used than on any particular nitrate of this class, or on the quantity of nitrate used.

When used with oils No. 1 and No. 17, which produce a high-grade concentrate without any reagent, the alkali metal nitrates lowered the grade of concentrate very noticeably, but when used with cresylic acid, which has a tendency toward making a low-grade product, these nitrates have practically no effect on the concentrate produced.

Alkaline Earth Nitrates

$Ba(NO_3)_2$. Nos. 20 to 23

Barium nitrate lowered the extraction about 4 per cent, regardless of the oil used. The effect of the grade of concentrate produced varied with the oil. Oil No. 1 lowered the lead tenor of the concentrate 18 per cent; oil No. 17 lowered the grade of the concentrate about 10 per cent; while with cresylic acid the concentrate was of practically the same grade as the one produced when no reagent was used.

The froths formed varied widely with this salt. With small quantities of barium nitrate, oil No. 1 gave a wet froth composed of medium-sized bubbles, which broke slowly, while larger quantities of this reagent gave a dry froth composed of large bubbles. With oil No. 17 the froth was very wet and had a long life. Cresylic acid produced a wet ephemeral froth, consisting of large bubbles, and the concentration was completed in 30 min.

$Ca(NO_3)_2.4H_2O$. Nos. 24 to 27

Calcium nitrate, when used with oils No. 1 and No. 17, had practically no effect on the extraction; but when used with cresylic acid the extraction was lowered about 7 per cent. The effect of this salt, when used with cresylic acid, on the grade of concentrate produced is practically nil, but when used with oils No. 1 and No. 17 the concentrate is lowered about 12 per cent.

The froths formed when using this reagent with oils No. 1 and No. 17 was composed of small, wet bubbles, which broke readily. With cresylic acid the froth varied from small, wet bubbles when small quantities of the reagent were used, to a dry, stiff froth with the larger quantities.

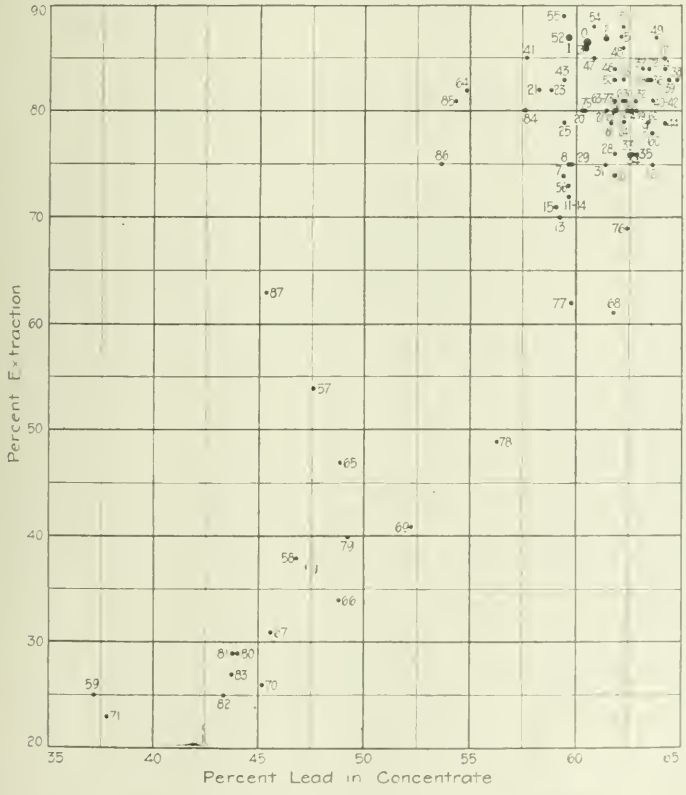

CHART 9—EFFECT OF NITRATES ON FLOTATION OF GALENA WITH CRESYLIC ACID

$Sr(NO_3)_2.4H_2O$. Nos. 28 to 31

The effect of strontium nitrate on both the extractions and grade of concentrates produced was very similar to those of calcium nitrate, regardless of the oils used. The froths which formed were likewise very similar to those of the corresponding calcium salt, with the exception that they contained more water.

$Mg(NO_3)_2.6H_2O$. Nos. 32 to 35

Magnesium nitrate is very similar in all its effects to the corresponding calcium salt.

When the alkaline earth nitrates are considered as a group, the results obtained correspond so closely with those obtained with the alkali metal nitrates that further discussion is unnecessary.

Metallic Nitrates

$Mn(NO_3)_2.6H_2O$. Nos. 36 to 39

Manganese nitrate lowered the extraction about 3 per cent, regardless of the oil used. The grade of concentrate was lowered about 16 per cent with oil No. 1, and about 4 per cent with oil No. 17, but with cresylic acid the concentrate was raised about 3 per cent.

The froth formed varied with the oil used. Oil No. 1 gave a wet froth, consisting of small bubbles; oil No. 17 gave a wet, ephemeral froth made up of medium-sized bubbles, and cresylic acid gave a dry, ephemeral froth composed of large bubbles.

$Ni(NO_3)_2.6H_2O$. Nos. 40 to 43

Nickel nitrate had practically no effect on the extraction when used with any one of the three oils. The grade of concentrate varied with the oil. When oil No. 1 was used the concentrate was lowered about 16 per cent. With oil No. 17 the concentrate was lowered about 14 per cent. The concentrate formed when cresylic acid was used was of about the same grade as that obtained when no reagent was present.

Oils No. 1 and No. 17, when used with 5 cc. of this salt, produced an ephemeral froth composed of very small bubbles. When larger quantities of the reagent were added, these oils produced a froth composed of very large bubbles, which had an exceptionally long life. Cresylic acid gave a dry, ephemeral froth composed of large bubbles.

$CO(NO_3)_2.6H_2O$. Nos. 44 to 47

With cobalt nitrate and oil No. 1 the extraction was lowered about 13 per cent. The effect of this salt is so nearly like the effect of nickel nitrate in all other respects that further discussion is unnecessary.

$Fe(NO_3)_2.6H_2O$. Nos. 48 to 51

The extractions obtained when ferrous nitrate was used varied more with the oil than with the quantity of the reagent added. With this salt and oil No. 1 the extraction was lowered about 17 per cent; when oil No. 17 was used the extraction was lowered only 4 per cent, while with cresylic acid the extraction is practically the same as when no reagent was present. The effect on the grade of concentrate produced was very slight. With oils No. 1 and No. 17 the concentrate was lowered about 3 per cent; with cresylic acid it was raised about 2 per cent.

The froths formed were very similar to those formed when nickel nitrate was used.

$Cu(NO_3)_2.6H_2O$. Nos. 52 to 55

Copper nitrate had practically no effect on the extraction when used with any one of the three oils. The effect on the grade of concentrate produced varied with the oil used. Oil No. 1 produced a concentrate which contained 22 per cent less lead than that obtained without a reagent. Oil No. 17 gave a 13 per cent lower grade concentrate, while cresylic acid gave a concentrate having practically the same composition as that obtained when no reagent was present.

The froth formed when copper nitrate was used with oil No. 1 consisted of very small, wet bubbles. Oil No. 17, when used with this salt, produced a froth composed of wet medium-sized bubbles, while cresylic acid produced a froth of very large, dry bubbles.

$AgNO_3$. Nos. 56 to 59

The results obtained when silver nitrate was used varied greatly. With oils No. 1 and No. 17, some of the extractions were lower than others, but this variation did not occur uniformly as the amount of silver nitrate solution was increased. With oil No. 1 the extractions varied from 10 per cent to 25 per cent low, while with oil No. 17 they varied from 8 per cent to 19 per cent low. The lead tenor of the concentrates with oil No. 1 was lowered about 10 per cent, while with oil No. 17 the grade of concentrate varied from 16 per cent to 20 per cent low.

When cresylic acid was used, both the extraction and grade of concentrate were lowered in accordance with the amount of silver nitrate present. When 5 cc. of the salt was present the extraction was lowered 14 per cent, while the lead tenor of the concentrate was lowered only 1 per cent. But when 50 cc. of the reagent was added the extraction was lowered 62 per cent, and the lead tenor of the concentrate 23 per cent. These results, when plotted, show a fair curve in which the extraction and grade of concentrate fall as the amount of silver nitrate is increased.

The character of the froths formed when silver nitrate was used varied widely. With oil No. 1 small amounts of this salt produced an extremely wet froth, but when the maximum amount of the salt was added the froth was exceedingly dry and very stiff. With oil No. 17 the froths were not as extreme as were those with the preceding oil. Cresylic acid produced dry, ephemeral froths composed of large bubbles which seemed to have very little carrying power.

$Pb(NO_3)_2$. Nos. 60 to 63

Lead nitrate, when used with oils No. 1 and No. 17, had no effect on the extraction, but when used with cresylic acid the extraction was lowered about 7 per cent. The concentrate produced follows the usual order, being about 17 per cent low with oils No. 1 and No. 17, and 2 per cent or 3 per cent high with cresylic acid.

The froths formed when this salt was used likewise follow the usual order; small, wet bubbles with oil No. 1 to large, dry bubbles with cresylic acid.

$Hg(NO_3)_2.H_2O$. Nos. 64 to 67

Generally speaking, mercuric nitrate had a detrimental effect both on the extraction and the grade of concentrate produced, regardless of the oil used. When used with oil No. 1, the extraction was lowered about 10 per cent, and the grade of concentrate about 22 per cent. When used with oil No. 17, the extraction was lowered about 18 per cent, and the grade of concentrate 20 per cent. When used with cresylic acid the effect on both the extraction and grade of concenrate is almost identical with the effect produced by silver nitrate.

The froths produced by mercuric nitrate were all wet, and varied only in the amount of water they contained.

$UO_2(NO_3)_2.6H_2O$. Nos. 68 to 71

Uranyl nitrate is another reagent which has a very detrimental effect on both the extraction and grade of concentrate produced. Its effect is very similar with all three oils, in that as the amount of uranyl nitrate solution was increased the extraction and the grade of concentrate were lowered.

There also seemed to be a relation between the character of froth formed and the extraction, in that the more water the froth contained the poorer the extraction. The froths formed very slowly, were very light, broke down quickly, and seemed to have no carrying power.

$Al(NO_3)_2.9H_2O$. Nos. 72 to 75

The effect of aluminium nitrate is practically the

same as with manganese nitrate, hence no further discussion is necessary.

$Bi(NO_3)_2.5H_2O$. Nos. 76 to 79

Bismuth nitrate, when used with oil No. 1, lowered the extraction about 5 per cent and the grade of concentrate about 15 per cent. When used with oil No. 17 and cresylic acid, both the extractions and the grade of concentrates were lowered as the amount of the salt was increased.

All the froths formed consisted of small, wet bubbles.

$Cd(NO_3)_2.4H_2O$. Nos. 80 to 83

Cadmium nitrate, like cadmium sulphate, had a very pronounced effect on the extraction and grade of concentrate, in that both were lowered enormously. When cadmium sulphate was used there seemed to be a marked relation between the amount of the salt present and the results obtained, but when cadmium nitrate was used this relation was not brought out so forcibly.

The froths formed with oil No. 1 and this nitrate were very wet, while with cresylic acid they were dry.

$Zn(NO_3)_2.6H_2O$. Nos. 84 to 87

Zinc nitrate lowered the average extraction about 12 per cent, and the grade of concentrate averaged about 8 per cent to 9 per cent low.

The froths formed varied from small, wet bubbles to large, dry bubbles, depending on the quantity of reagent added and the oil used.

Summary of Effect of Nitrates

The nitrates used, when considered as a whole, gave widely divergent results, which seemed to depend more on the oil than on any other factor.

When oil No. 1 was used the average extraction, with a few exceptions, was practically the same as when the oil was used without any reagent, but the average grade of concentrate produced was lowered about 17 per cent.

When oil No. 17 was used, the average extraction was lowered slightly, while the grade of concentrate was lowered from 8 per cent to 10 per cent.

With cresylic acid, the average extraction was lowered about 7 per cent, but the grade of concentrate produced was raised 2 per cent or 3 per cent.

The nitrates had a very striking effect on the character of the froth formed. When used with oil No. 1, the froth was usually composed of small, wet bubbles. In a few cases the bubbles were so small that the froth resembled a thick scum.

When oil No. 17 was used, the bubbles were larger and the froth was not so wet as that produced with oil No. 1.

When cresylic acid was used, the froth was usually dry, and composed of large bubbles, which seemed to have very little carrying power.

Work of the British Nitrogen Products Committee

Plans Under Way for Cyanamide, Ammonia, Oxidation, and Experimental Synthetic Ammonia Plants

ENGLAND has attacked the nitrogen problem much the same as the United States. A Nitrogen Products Committee was formed in June, 1916. following the formation of the Munitions Inventions Department. The Ministry of Munitions has recently issued a memorandum on the nitrogen problem and the work of the Nitrogen Products Committee, which we herewith reproduce from the Journal of the Society of Chemical Industry.

The Nitrogen Problem

The manufacture of the vast quantities of explosives that have been called for by the present conditions of warfare has led to an unprecedented demand for various nitrogen compounds. The world's consumption of nitrogenous fertilizers appears practically to double every ten years, and in 1913 had attained the large figure of 2,500,000 tons of Chile nitrate and about 1,400,000 tons of ammonium sulphate.

With the outbreak of the war the demand for explosives became of paramount importance and the requirements of agriculture for the time being took a secondary position. The prospect of world shortage of food, however, has served to bring the agricultural aspect of the problem again into the forefront. The researches of Sir William Crookes and of Lord Rayleigh upon the fixation of atmospheric nitrogen by means of the electric arc pointed the way to a method of utilizing the unlimited supply of nitrogen in the air.

The establishment on a very large scale during the past 20 years of processes for nitrogen fixation is one of the most striking electrochemical developments of modern times. Special reference may be made to the arc process, as used in Norway, the Haber or synthetic ammonia process developed in Germany, and to the cynamide process for the manufacture of nitrolim from calcium carbide, as carried on in Norway, Sweden, France, Italy, Germany and the United States.

In spite of the fact that the incentive to the commercial establishment of nitrogen fixation may be said to have originated in this country, no steps were taken in the United Kingdom to obtain nitrogen compounds other than cyanides synthetically. The ammonia recovered at gas works and coke ovens has constituted practically the only form of combined nitrogen produced in this country. During the war the command of the seas has hitherto enabled Great Britain to rely entirely upon importation for the whole of our supplies of nitrate of soda, the most important raw material of our explosives industry. The Central Powers, on the contrary, having been cut off from external supplies, were compelled to fall back upon their internal resources, with the result that nitrogen fixation processes, some of which were established commercially before the war, have been developed upon an enormous scale.

Soon after the formation of the Munitions Inventions Department in August, 1915, proposals for the fixation of nitrogen began to be received from inventors. These schemes were referred to the Chemical Inventions Com-

mittee of the Advisory Panel, but as they were isolated applications of the general problem and were of limited scope they did not immediately lead to any definite line of policy being taken upon the question. The importance of the problem was recognized, however, and the attention of the Minister was directed to it from time to time in the monthly departmental reports.

The inauguration of the submarine campaign in February, 1916, and the grave menace to overseas supplies of nitrates emphasized the importance of taking action on the matter. At this opportune moment a memorandum on the nitrogen problem was submitted to the Department by the Faraday Society. Several conferences were held to discuss the steps that should be taken, and, as a result, the Nitrogen Products Committee was constituted in the following June. Members of the Advisory Panel, representatives of other Departments of the Ministry of Munitions and of the Government, and delegates of the leading scientific societies were invited to serve. The terms of reference were:

(1) To consider the relative advantages for this country and for the empire of the various methods for the fixation of atmospheric nitrogen from the point of view both of war and peace purposes; to ascertain their relative costs, and to advise on proposals relevant thereto which may be submitted to the department.

(2) To examine into the supply of the raw materials required, *e.g.*, pure nitrogen and hydrogen, and into the utilization of the by-products obtained.

(3) Since some of the processes employed depend for their success on the provision of large supplies of cheap power to ascertain where and how this can best be obtained.

(4) To consider what steps can with advantage be taken to conserve and increase the national resources in nitrogen-bearing compounds and to limit their wastage.

(5) To carry out the experimental work necessary to arrive at definite conclusions as to the practicability and efficiency of such processes as may appear to the committee to be of value.

(6) As a result of the foregoing steps to advise as to starting operations on an industrial scale.

An important advance was made when the then Minister of Munitions, the Right Hon. E. S. Montagu, M. P., met the members of the committee on October 10, 1916. He assured them that the Government appreciated the importance of the nitrogen problem, and that he would do everything in his power to see that the recommendations ultimately made received the fullest consideration. At this meeting Sir William Crookes was able to be present. At the same meeting the organization of the committee was completed, and the following sub-committees were set up: Processes, Economics, Experiments, Power and General Purposes.

At a later date another sub-committee was found necessary to deal with the question of coal distillation processes and the production and utilization of power gas. The Gas Firing Sub-Committee was accordingly constituted. In all the committee and its sub-committees have held upwards of eighty meetings.

The necessity for research was evident from the outset, and the department at once took steps for the organization of a suitable research staff and the acquisition of a laboratory. Fortunately, the co-operation of the authorities of University College was secured, and a part of the new Ramsay Laboratory, at that time scarcely completed, was placed at the disposal of the department.

Nitrogen Fixation Research

The item placed first on the research programme was a complete investigation into the production of synthetic ammonia by the Haber process. The decision was influenced by the claims made for the process and by the commanding position it occupies in Germany, where the economic conditions as regards coal supplies and the comparative absence of water power are similar to those in Great Britain. Moreover, the almost complete lack of precise information concerning the commercial details of this process made it apparent that the research would present many unknown factors, and was therefore likely to occupy a considerable time.

Towards the end of the year the committee came to the conclusion that the ammonia oxidation process was well adapted as an emergency measure for securing quickly a considerable output of nitric acid or nitrates. Although already working with more or less success upon the Continent the process had not at that time been operated in this country. A systematic investigation of the most recent developments of the process was therefore undertaken.

Many important problems have arisen in connection with the two main researches indicated above. Reference may be made to such questions as the most efficient and commercially practicable catalysts for the synthesis of ammonia and for ammonia oxidation, and the commercial preparation in bulk and at a sufficiently low cost of hydrogen of the high degree of purity required for the synthesis of ammonia.

On account of the formidable technical difficulties presented by the different problems it was obvious that a research staff of considerable experience in all the recent developments of physical chemistry was needed for carrying quickly to a successful issue the work of the research program. In the selection of the personnel, therefore, endeavor was made to obtain men possessed of special qualifications. The department has been fortunate in securing a number of such men, with the result that the progress made has been more rapid than might have been expected under the present difficult circumstances. It may be mentioned that the chemist responsible for the research on the synthesis of ammonia had the advantage of having previously worked for some time on the problem at Professor Haber's laboratory at Karlsruhe.

In December, 1916, when the research work was in its early stages, a demonstration and lecture took place at the Research Laboratory and was attended by representatives of the Explosives Supply Department and of the War Office, and by delegates and members of other Government departments and of scientific societies. The Minister of Munitions was unable to be present, but early in 1917 he asked for practical recommendations to be submitted to him at any early date.

In view of the magnitude and complexity of the problem the committee was unable immediately to present a complete report. Certain definite conclusions had been arrived at, however, and these, together with recommendations thereon, were embodied in a unanimous

interim report which was submitted to the Minister of Munitions in February, 1917. The substance of the recommendations is given below:

Interim Report of the Committee

(a) *By-product Ammonia.*—The importance of increasing the output of by-product ammonia for munitions and for agriculture was pointed out. Steps were indicated whereby an increase could be obtained from existing gas works and coke oven plants. It was also recommended that action should be taken to avoid the loss of ammonia known to be occurring in certain districts.

(b) *Ammonia Oxidation Process.*—The erection at the earliest possible moment of plant capable of producing in the aggregate at least 10,000 tons of nitric acid per annum from gas works or coke oven ammonia was recommended

(c) *Cyanamide Process.*—The erection of a factory having an annual output of the order of 50,000 tons of cyanamide was recommended, the cyanamide to be utilized as such for agriculture or for the production of ammonia.

(d) *Synthetic Ammonia Process.*—The erection of a full-sized trial unit plant for synthetic ammonia process was recommended.

The Minister of Munitions invited members of the committee to meet him, and the recommendations of the interim report were discussed in detail. At the conclusion of this meeting the Minister appointed a small Executive Committee to supervise the action involved in giving effect to his decisions, and to report to him from time to time upon the progress made.

The Minister's Decisions and the Action Taken Thereon

The Minister's decisions were as follows:

(a) *By-product Ammonia.*—The committee was requested to deal with the problem of conserving ammonia and of augmenting the output on the lines of the recommendations.

(b) *Ammonia Oxidation Proccss.*—The Ministry of Munitions would undertake the installation of one Government plant on the lines suggested, or if the committee so advised the Ministry would agree to the erection of plants by suitable private firms. The information resulting from the research work was to be placed freely at the disposal of *bona fide* manufacturers, but was not to become the exclusive property of any firm or group of firms.

(c) *Cyanamide Process.*—The committee was requested to investigate the relative merits of a Government scheme and of other schemes that had been put forward involving private enterprise and to submit a report embodying definite proposals.

(d) *Synthetic Ammonia Process.*—The erection of the full sized trial unit was authorized.

In carrying out these decisions the Executive Committee dealt first with the problem of conserving and increasing the output of by-product ammonia. The co-operation of the Controller of Coal Mines, of the gas companies and of the domestic and industrial users of coke was enlisted, and the matter was then placed under the direction of the Explosives Department in March, 1917, in view of its existing organization for dealing with the supply of ammonia.

The next step taken was to summon a conference of manufacturers likely to be interested in the ammonia oxidation process, as a good deal of information had been collected regarding it and the research work had already reached a semi-commercial stage. Conferences took place at the Munitions Inventions Department in March, 1917, and were attended by representatives of a number of the more important interests. Several manufacturers at once agreed to take up the further study of the process with a view to its commercial development, and have since actively co-operated with the department. Some of them have already erected experimental plant on a considerable scale.

Encouraging progress continued to be made with the research, and arrangements and plans were made for the erection in London of a trial plant consisting of a single commercial unit designed to give an output of one ton of strong nitric acid per day. At this stage the work of establishing the process on a commercial scale for the manufacture of nitric acid and ammonium nitrate was handed over to the Explosives Department at their request in August, 1917. The work of investigation, however, has been continued at the Research Laboratory, as several important aspects of the process still remain to be explored.

With regard to the manufacture of cyanamide the Executive Committee came to the conclusion that the schemes involving private enterprise did not adequately fulfill the ends in view and recommended the erection of a factory by the Government. The committee proceeded to collect further information on cyanamide processes in actual operation and representatives proceeded overseas for this purpose. Complete details of a scheme involving a large scale factory with electric power station are now in course of preparation for submission to the Minister of Munitions.

Meanwhile a considerable amount of work had been carried out in connection with the synthesis of ammonia, including a detailed investigation of the whole of the conditions governing the process and of the efficiency and life of numerous catalysts. These studies led to the devising of a method of working whereby the output of ammonia per unit of catalyst space has been increased to a figure, which, as far as is known, exceeds anything hitherto attained. The design and erection of a semi-technical unit apparatus embodying a number of novel features, with the necessary pumps, circulators, gas holders, etc., was then undertaken. It is expected that the operation of the unit, which is now at work, will enable the remaining problems as to the chemical engineering details involved in the design of the full sized trial unit authorized by the Minister to be definitely settled.

Research upon the preparation of pure hydrogen in bulk has been carried on conjointly with the above investigations and arrangements have already been made for the trial on a semi-commmercial scale of a process that has given very promising results in the laboratory.

Nitrogen in Sulphuric Acid Manufacture

An important practical outcome of the conferences with manufacturers has been the introduction of ammonia oxidation plant to take the place of the nitre pots used in the manufacture of sulphuric acid by the lead chamber process. In pre-war times the annual con-

sumption of Chile nitrate for this purpose amounted to 18,000 tons. With the present increased output of sulphuric acid the consumption is greater, so that the possible saving of overseas freight is appreciable.

One of the small converters designed in and made for the Department Research Laboratory has been installed at the sulphuric acid works of Messrs. Brunner, Mond & Co. and has been working satisfactorily for some months. The firm is now arranging to adapt similar converters to the whole of their lead chambers. The United Alkali Co., the South Metropolitan Gas Co. and others are making arrangements to adopt the process and are utilizing two types of converter to the laboratory designs. Drawings have also been placed at the disposal of the Explosives Department for the benefit of other controlled establishments.

The apparatus is compact; the expense involved in its installation, apart from ammonia purification plant, is comparatively small, and its operation is simple. Arrangements have therefore been made for the rapid manufacture of the converters likely to be required, since it is believed that these designs may become standard types for the purpose in question. An explanatory pamphlet, compiled by the research staff and embodying detailed information concerning the construction and operation of the converters, will be available shortly for the use of firms who have already taken up the process or are desirous of doing so.

Further Research

Up to the present date the research has practically been confined to the two processes mentioned above and to problems arising therefrom. The investigations of the committee have shown, however, that many important and promising fields still remain to be explored.

Under present circumstances all activities have been concentrated upon processes which have a possible value as war measures and no attempt has been made to extend the programme of research beyond such limits. In view, however, of the national importance of the nitrogen problem, both now and in the future, it is hoped that definite arrangements will be made to preserve the continuity of the research after the war.

The Importance of Cheap Electric Power

It was recalled from the outset that the generation of electric power at a cost decidedly lower than has hitherto been attained in this country was a vital factor if an attempt was to be made to establish certain of the nitrogen fixation industries in Great Britain on a sound economic basis from the point of view of post-war competition. A thorough inquiry has therefore been made as to the possibility of cheapening the production of electric power from coal, not only by its generation in bulk with the most modern plant, but also by the use of methods involving carbonization and gasification, with recovery of the ammonia, fuel oils and other by-products hitherto wasted when raw coal has been directly used. The sub-committees concerned have had the advantage of obtaining the personal views of a number of experts who attended to give evidence on different aspects of the problem. This inquiry has been distinctly fruitful, and much detailed information has been collected.

Schemes for the utilization of various undeveloped water powers in the British Islands for nitrogen fixation have also been submitted and have been carefully examined. At least one of these schemes for hydro-electric development on a considerable scale presents *prima facie* prospects of becoming a valuable national asset. The Power Sub-Committee recommended that a survey should be made of the drainage area in question with a view to confirming the details of the scheme as submitted. The survey has recently been completed and is expected to result in the formulation of a definite development scheme for the utilization of this water power. It is estimated that the engineering work involved will take about two years to complete, and the scheme is therefore to be regarded as a post-war measure.

Costs of Operating Nitrogen Fixation Processes

Since many of the nitrogen fixation processes have not only a value for munitions but also a post-war importance, endeavors have been made to investigate the probable requirements of this country for nitrogen requirements of this country for nitrogen products. A detailed examination has been made of the production, consumption, imports and exports of such products, and special consideration has been given to the question as to the relative order of the costs involved in operating the synthetic and non-synthetic processes.

Most of the information relating to synthetic processes has had to be obtained from foreign sources, and the committee has been able to secure many figures of an authoritative character. The information thus collected has been subjected to critical examination in the light of manufacturing experience in allied industries and conclusions have been arrived at as to the costs likely to be incurred under British conditions.

The magnitude of this part of the inquiry may be measured when it is stated that the committee is in possession of comprehensive data concerning the cost of manufacture of:

(a) Nitric acid and nitrates by the older methods, and by the arc and ammonia oxidation processes.

(b) Calcium carbide and cyanamide.

(c) Ammonia and ammonium sulphate by the Haber and cyanamide processes.

(d) Hydrogen and nitrogen.

As well as concerning the costs involved in operating the Chili nitrate and the by-product ammonia industries.

Co-operation with Other Government Departments

Realizing that many of the branches of the committee's activities related to problems which were also occupying the attention of other Government departments, an attempt has been made to secure as far as possible co-operation and interchange of information. Thus on the question of the carbonization of coal, an exchange of views has taken place with the Fuel Research Board. On the question of the production of hydrogen on a large scale at the lowest possible cost a problem of great importance in connection with aeronautics, collaboration in experimental work with the Admiralty has been arranged. It will be noted that the constitution of the committee has provided for liaison with the Explosives Department, the Board of Agriculture, the Board of Trade and a number of scientific societies.

In accordance with the terms of reference the final report of the Nitrogen Products Committee will include

a review of the nitrogen problem as it affects the British Empire. This branch of the work has not yet been fully dealt with, but representations have been made to the Dominions, to dependencies (through the Colonial Office), to Egypt and to India informing the governments concerned of the activities of the committee and offering to place at their disposal all the information in the possession of the department.

As a result of the negotiations thus instituted the department is already in direct touch with official representatives of the Governments of Australia, Canada, New Zealand, South Africa, Africa, Egypt and Mysore, and also with important developments in other parts of India.

Nitrogen Fixation in Allied Countries

An interesting event was the visit to this country in February, 1917, of a delegation from the recently constituted Commission de l'Azote acting under the French Ministry of Munitions. It was soon evident that the delegation was most immediately interested in the various processes already established in this country for the manufacture of ammonium nitrate, and a visit of inspection to many of the controlled establishments was accordingly arranged through the Explosives Department.

Several conferences with the delegates were held at the M.I.D. during their stay in this country, and an interchange of ideas and information took place upon the most recent developments in nitrogen fixation in France and Switzerland. The entente thus established has been maintained by the periodical exchange of information and documents between the French Ministry of Inventions and the Munitions Inventions Department.

The Allied Governments of Italy and Russia have also nominated representatives to act in liaison with the department upon the nitrogen problem. The developments already accomplished in the countries in question have enabled these liaison officers to afford immediate and valuable assistance.

The action taken by the United States Government on the nitrogen question is also worthy of notice. Under the National Defence Act of 1916 a sum of £4,000,000 was set aside for the establishment in the United States of nitrogen fixation on a large scale. Committees of the Academy of Sciences and afterwards of the Ordnance Department were set up. Their advisers visited England, and the more important nitrogen-fixation installations on the Continent outside Germany. Upon the recommendation of their experts the U. S. A. War Department has decided to erect forthwith works for the manufacture of synthetic ammonia by a modified Haber process.[1]

Final Report of the Nitrogen Products Committee

The various sub-committees set up by the Nitrogen Products Committee have already completed or are now engaged upon their final reports. There will then remain the report of the main committee, which will of necessity be a somewhat detailed document owing to the scope of the inquiry that has been undertaken. Endeavors are being made to expedite the last stages of the work so that the final report may be available at the earliest possible date.

[1]Editor's Note: The War Department is also building a large cyanamide plant at Muscle Shoals. See our issue of Jan. 1, 1918, p. 1.

Current News and Notes

New Jersey Industries on War Basis.—New Jersey is the first state in the United States to undertake the organization of its manufacturing industries on a war basis, with the object of assisting the Government, and this step was taken Dec. 19 at the War Convention of the Manufacturers' Council of the New Jersey State Chamber of Commerce, held at the Robert Treat Hotel, Newark. The iron and steel industry was represented by L. S. Ayre, International Motor Co., Plainfield, N. J., and Arthur E. Barlow, Barlow Foundry Co., Newark.

Composition of Canadium.—Canadium is a composition alloy composed of 70 parts tungsten and 30 parts chromium, annealed. Trade name Canadium, sold by The Franklin Chemical Co., Ltd., London, England.

Chemists' Club for France.—An organization has been effected in France to be known as the Cercle de la Chimie, and will maintain headquarters at 54 rue de Turbigo, Paris. The *Revue des Produits Chimiques* will be the official organ of the Cercle de la Chimie. The club building will contain a reading room, a writing room, a lounge room and all the conveniences and comforts of a modern club. Provision is made for the holding of scientific meetings, and extensive literature will be available. Chemists and chemical engineers who go to France will welcome the opportunity to visit this club.

Colorado Scientific Society.—At the thirty-fifth annual meeting of the Colorado Scientific Society the following officers were elected to serve during 1918: President, Dr. Richard B. Moore; first vice-president, Mr. Lewis B. Skinner; second vice-president, Mr. Marmaduke B. Holt; treasurer, Mr. John W. Richards; secretary, Mr. Harry J. Wolf; executive committee: term expires Jan. 1, 1921, Mr. J. Claire Evans and Mr. M. S. MacCarthy.

Manganese Ore at Butte, Mont.—A reconnaissance of the Butte district was made recently by J. T. Pardee of the U. S. Geological Survey, who reports that the development of manganese ores at Butte has heretofore been wholly incidental to the production of silver, zinc, and lead, in the ores of which manganese minerals are among the chief components of the gangue. Except a few small lots used for fluxing at the smelters, no manganese ore was mined for manganese prior to 1917. As ores containing less than 25 per cent silica are rare in the district, the development of the lodes for manganese has lagged behind that in localities which produce ore of better grade. Systematic exploration of several of the larger manganiferous lodes has just begun, and search for pockets of marketable ore is being made in a small way by several lessees. The manganese ore is mostly oxidized and siliceous, and its content of manganese ranges from 10 to 37 per cent, but there are small quantities of high-grade ore, both oxide and carbonate. The main problems to be solved before Butte can become a factor in the manganese market under present conditions are (1) successful milling of the ores to produce a low-silica concentrate, and (2) briquetting the concentrate or otherwise making it acceptable to buyers. Milling tests have already been begun, but the results have not been entirely satisfactory, owing chiefly to losses in the tailings by sliming.

The Sulphuric Acid Situation in the United States

By LEWIS B. SKINNER*

PRECEDING the declaration of war, sulphuric acid in the United States was made exclusively either from "burner gases," produced in roasting zinc ores (blende) or pyrites, or from blast-furnace gases from the smelting of Tennessee copper ores. The pyrites-burning plants were situated more particularly along the Atlantic Coast, in the Southern fertilizer manufacturing areas, and on the Pacific Coast. Blende-roasting plants were situated in those Middle-Western districts where cheap coal and natural gas are available. In general, pyrites was obtained from three places: Spain, Canada and Virginia. After the war began, the Spanish supply was materially reduced and the Virginia supply has been curtailed as a result of a cave-in and flooding of the Arminius mine, Virginia's principal producer. Consequently a number of manufacturers have found it necessary to burn brimstone instead of pyrites. Fortunately for the United States we have two internal supplies of brimstone which were capable of immediate expansion to several times their former production.

For a while after the war was started the Southern fertilizer plant, with its adjunct of acid chambers, was curtailed in its production of complete fertilizer, and the acid plant was turned over to intense production for sale to powder makers. A number of small chamber plants, which had been built in connection with fertilizer factories, had been shut down before the war because it was commercially cheaper to purchase acid from some of the large producers, such as the Tennessee Copper Company, than to make this commodity on a relatively small scale. When the war demand came on these plants were put in as good shape as was practicable and started up, because, with soaring acid prices, it was quite profitable to operate plants that were almost ready for dismantling.

Production from Zinc-Acid Plants

The zinc-acid plants also were stimulated with equal intensity in both of their outputs, with the result that every possible arrangement for increased production was resorted to, even though recoveries were not good. Even Hegeler kilns, which are used almost exclusively in the United States for roasting ores in zinc-acid plants and which are known to demand a high amount of oxygen to finish the roast, were arranged to burn brimstone along with ore so as to increase acid production. The normal operation of these kilns for acid making results in the production of a weak gas, so that the chambers in such plants have to take care of an oxygen content far higher than that necessary for the actual chamber reactions. A suggestion to a number of such operators that melted brimstone be fed into the dust flues on top of the roaster, thus utilizing the otherwise objectionable excess of oxygen and securing greatly increased production for the same sized chamber layout, was followed. This procedure increased the chamber capacity about 20 per cent, other things being equal, and the practice soon spread to all zinc-acid plants. The high prices of zinc and acid prevailing shortly after the beginning of the war stimulated the addition of chambers, retorts and roasters in almost all of the zinc-acid smelters making sulphuric acid as a by-product. With the increased demand from the explosives manufacturers, steel makers, oil refiners and others, the demand for sulphuric acid has seemed to be unlimited and, throughout the war so far, its production has not caught up to the demand.

The zinc smelting plants that are situated in the Kansas-Oklahoma gas belt do not utilize the sulphur gas produced from roasting, because it is commercially practicable to roast by burning natural gas in direct contact with the ore. This practice commingles the products of combustion and the sulphur gas, so that the latter is not available for acid making. Further, it is considered financially risky in this district to make a greater investment than necessary, with short-lived gas pools controlling the situation.

Coal-burning plants, on the other hand, have a much higher investment cost both on account of the need for gas-producer equipment and the necessity for using expensive muffled roasters, or kilns, so as to avoid the relatively high volatilization loss of zinc when burning coal in a "reverberatory" style of working. Since these kilns prevent the commingling of the products of combustion and the bases resulting from the oxidation of the ore, the latter may be used for making sulphuric acid, thus giving us what are called zinc-acid plants.

The sulphur-bearing zinc ores of this country are found mainly in Missouri, Wisconsin, Montana, Colorado, Tennessee and California. With the exception of Tennessee the zinc ores available to our reduction plants came mainly from west of the Mississippi, and freight rates settled the advantageous smelting points near cheap coal supplies in Illinois. The pre-war American market could absorb only a limited amount of spelter, and exportation was impracticable because about 60 per cent of the world's consumption of the metal was more cheaply furnished by Australian ores finding cheap water transportation to Belgian smelters. Zinc acid did not begin to cover the requirements of the United States, but even if the demand for spelter had been such that there could have been a greater coincident production of sulphuric acid, it was practically impossible for a commodity of this low value to be transported any great distance by railroads under existing freight rates. That there have been gradual changes in the geographical location of zinc-acid plants should be noted in a general panoramic view, for two zinc-acid makers have invaded the Pittsburg district with very large plants, one of them formerly a very large customer of acid manufacturers, and two others

*Vice-President and General Manager, Western Chemical Mfg. Co., Denver, Colo.; Consulting Chemical and Metallurgical Engineer, Central Construction Corporation, Harrisburg, Pa.

are now operating in close proximity. Ores from Australia, not being utilized by the Germans just at present, are finding a very satisfactory market at these Eastern smelters. It would seem as if ocean freight rates are such as to allow of a continuation of this business even in normal times.

In the United States brimstone acid is usually the most expensive; that made from lump pyrites is probably second in cost; that from "pyrites fines" is third; while zinc acid is the cheapest. The metallurgy of zinc makes demands upon equipment investment and per-ton cost of handling which is the greatest of any of the ordinary metals. It makes technological demands which leaves the cost of by-product sulphuric acid anything the policy of the company may wish it to be. It is a metallurgical fact that the losses of metal in open roasting as opposed to muffled roasting, using producer gas from coal as fuel, are such that muffled roasting would be desirable even if the resulting sulphur fumes were not utilized. Since muffled roasting in this case is a necessity to avoid volatilization of zinc, a sulphuric acid plant which demands a relatively clean and strong gas naturally follows. Since the roasting has to be done on such a high-priced commodity as high-grade zinc concentrate, it ordinarily really matters little whether the gases are handled to make sulphuric acid or not. The factor that controls this in normal times is that such gases turned into the atmosphere of communities where zinc smelters usually are located would be a nuisance. Other things being equal, it is preferable to avoid trouble. While this fear of committing a nuisance has been a very valuable asset to the United States under war conditions, it will cause some concern when normal times come, because, in order to handle the ores, the gases will be produced and the acid will be made. Some strenuous endeavors will have to be made by sales forces, and, incidentally, traffic departments working with the railroads, in an endeavor to dispose of this by-product acid into a territory which may be expanded in proportion to the expansion that the zinc smelting industry has undertaken as a result of the war stimulus.

Acid from Other Metallurgical Sources

There has been no material increase of acid capacity in any other metallurgical line than that of burning pyrites bearing valuable metals and that of zinc blende. It should not be considered, however, that pyrites and blende, along with brimstone, are the only sources of suitable gas for acid manufacture. Two of our large copper smelters have been making large tonnages of acid from the fume evolved from blast furnaces. These two companies have used what is called semi-pyritic smelting. Since the war started two installations have been completed where copper ores will be used as the source of supply for the acid gases. Both of these are using easily roasted, high-iron, low-copper, sulphide minerals in a roasting process that is easily comparable with that of ordinary clean iron pyrites.

With the demand for relatively clean and concentrated gas there cannot be much hope for the utilization of lean, dirty gas produced from ores ordinarily handled in lead smelting practice. This would not apply, of course, where part of the ore used could be iron pyrites relatively free from lead. It should be appreciated that the satisfactory roasting of ores for acid making is a far different proposition than roasting merely to create a desired metallurgical condition. In acid roasting no large excess of air may be allowed to pass through the roaster, and this restriction permits the development of high temperatures which, in the case of leady ores, causes the volatilization of a large part of the metal, whereas in a metallurgical roast large volumes of air are caused to pass through the roaster, so cooling it down to a point which makes such roasting easily manageable.

The large part of the United States demand for acid comes from those states near the Atlantic Ocean and those Southern states in which the soil demands fertilization. To take care of this numerous plants were operated in these areas by burning iron pyrites solely for the purpose of furnishing gas for acid making, using varieties from the sources mentioned before which roast very easily, either in lump burners or in mechanical fines furnaces. By so doing the process of acid making is very simple indeed.

In general it may be said that sulphuric acid can be most easily made by using brimstone and that the difficulties of manufacture increase in the following order:

(a) Burning clean pyrites in lump burners.

(b) Burning clean pyrites in mechanical furnaces.

(c) Roasting sulphide mixtures (i. e., mixtures of iron, lead, zinc, etc., with sulphur).

(d) Dead-roasting zinc blende in kilns; and, finally,

(e) Utilizing waste sulphur gases from metallurgical operations with the likelihood that dilution and obnoxious volatile constituents will have to be fought.

Where pyrites was bought for acid-making it was usually purchased on the basis of a price per unit of sulphur, which, at the various points of consumption before the war, probably would average eleven cents. Under the "price per unit" system the given price applies to each per cent of sulphur in the pyrites, and the price per ton of ore is accordingly determined by multiplying the unit cost by the percentage of sulphur as found by analysis.

The "cinder" or roasted ore resulting from burning pyrites was usefully applied in one of three ways: The Spanish cinder was shipped to a chloridizing-roasting copper-leaching plant operated by one of the large acid manufacturing companies; the barren cinder was sent without any further treatment to iron blast-furnaces, where it was more suitably prepared for iron manufacture by being further desulphurized to 0.2 or 0.3 per cent sulphur by blast-roasting; or, was used for road building, complete fertilizer filling, etc. A number of small acid plants were not and are not yet storing this material, which is apparently waste to them, but this practice should not be continued, because there will be a time not far distant, if it is not already here, when a metallurgist can suggest a course of procedure which will show a profit.

Brimstone vs. Pyrites

The American demand for sulphur has increased, and strenuous times are at hand at this writing for reasons already given. With so many manufacturers already having changed from pyrites to brimstone burning, it would be remarkable were our brimstone supply elastic enough to take over all the additional load. We are to be congratulated that our Union Sulphur and Free-

port Companies have been able to expand their former output many times.

There are brimstone deposits in Wyoming, near Cody and Thermopolis, but the rock does not occur in large quantities in the individual pockets, nor is it of a sufficiently high grade. It will probably average 30 per cent sulphur in workable deposits.

The substitution of brimstone for pyrites in a number of plants that have been burning the latter has enabled these manufacturers to produce a greater tonnage of acid from a given sized unit. When brimstone is used as a source of sulphur dioxide, the plant investment per ton of acid produced is far less, other things being equal, than when acid is made from pyrites. The reason for this is that the burner construction is much simpler, the gas resulting from brimstone is far richer and so demands less chamber space per pound of sulphur burner than in the case of pyrites. In burning the latter, part of the oxygen entering the roaster, or the lump-burner, as the case may be, is consumed in oxidizing the iron that is a constituent of pyrites. The nitrogen, of course, that enters with this oxygen, passes on with the sulphur dioxide gas that results from the oxidation of the sulphur and acts as a diluent in the burner gas. With brimstone there is no other material to be oxidized, and therefore the air that passes in for oxidation furnishes only a sufficient amount of oxygen for the brimstone itself. Burner-gas from pyrites may carry 8 per cent SO_2, whereas that from brimstone may run 12 per cent.

In normal times, and even under the present circumstances, the sulphur in brimstone is more expensive than that in pyrites, but, on account of the lack of boats for the transportation of Spanish pyrites and the accident to the large Virginia supply, the manufacturer has little option to do otherwise than buy the more expensive brimstone. One ton of brimstone will make practically three tons of 66 deg. Be. acid, or four tons of 60 deg. Be. acid. If the brimstone is sold at a cost approximating $36 a ton delivered, it may be easily computed that this cost alone against 66 deg. acid is approximately $12 per ton, and that the cost of the brimstone in 60 deg. acid is $9 per ton. The increased investment and operating cost per ton of 66 deg. acid made from pyrites as against brimstone is approximately $2 per ton. This would compare now with a pyrites price of approximately 32 cents per unit, calculating for the roaster losses. The differential between brimstone and the sulphur in pyrites is even now, therefore, great enough to permit of the use of pyrites, even though less acid is made in a given plant and even though the plant investment costs more per ton, as rarely is 30 cents per unit asked. In a "speed-up" policy our Government is asking for as large a production as possible, so brimstone is now used as far as possible for patriotic as well as commercial reasons.

The Contact Process

A decade or so ago there was quite a controversy among acid makers on the relative merits of the contact and chamber processes. It was even predicted at that time that the chamber process could not long survive and that the contact would be the only one used.

The situation in the country developed as follows: The General Chemical Company secured the American rights for the "Badische" contact process, the New Jersey Zinc Company for the "Grillo-Schroeder" process, Mr. Wilke of Buffalo, N. Y., for the "Mannheim" process and the Merrimac Chemical Company for the "Tantelewski" process. Sulphuric acid production continued to be largely the result of the use of the chamber process for the reason that the plan of licensing was usually made both onerous and annoying, onerous in that the royalties exacted were relatively heavy, more particularly on the stronger grades of product, and annoying for the reason that most licenses proposed were in such form that the licensor would have every opportunity of learning exactly what the licensee's business amounted to. Since it was not deemed advisable to place this information in the hands of competitors, there was a disinclination on the part of most manufacturers to use the contact process.

Later on, as a result of European litigation, the American rights for all of the four contact processes virtually passed into the control of one company, whose American representative is the General Chemical Company.

General Plant Equipment

With acid making tending to pass over to various ore smelters and with fine concentrates from flotation mills and their reduction plants creating clouds of dust in the roaster gases, much money has been spent in an endeavor to adapt the Cottrell precipitation process to handle the gases used for acid manufacture. In the chamber process it is desirable to have the roaster gas remain as hot as possible in its passage to the Glover tower. In roasting material containing iron a small percentage of the sulphur is converted catalytically, under the effect of the roast, to sulphuric anhydride, and this, of course, will combine with the moisture present in the air admitted to the gas, with the result that sulphuric acid will be precipitated in flues if the gas becomes cool. To maintain a lot of metallic parts at red-hot temperature, to avoid the corrosion that takes place when the temperature drops, and to maintain a delicate equipment in commission when either one or the other condition is likely to prevail present difficulties, particularly when one is trying also to prevent the leakage of voltage which is not within the realm of ordinary usage. This has caused the Cottrell scheme to be abandoned in the acid works where it was tried. Some good dust-collector designs, however, have been perfected and are so simple that these may be placed in the hands of the ordinary operator. The manufacture of sulphuric acid by either process, the contact or the chamber process, demands an approximation to that condition which we call "fool-proof," and with this idea the Cottrell does not comply.

Mechanical roasters of the McDougall type have been greatly improved in their ability to avoid "lost time." Numbers of modifications of design permit of use in almost any wide range of metal content in sulphide ores and products. In acid manufacture the ability of this type to conserve heat has driven all but the old Hegeler kiln (for dead-roasting zinc blende) out of the market, and the near future will no doubt see this type slowly displacing even the Hegeler. The construction of the old fashioned lead tower in chamber plants is rapidly giving away to far cheaper masonry designs, and the old crockery pipes, containers, cocks and pipelines to the silicon-iron castings.

Variety of Demand for Sulphuric Acid

I can recall no explosive (with one exception, black powder) which does not depend upon sulphuric acid in some form for its manufacture. Of course, all explosives demand nitric acid or nitrates in their manufacture. To take up the water both of the original nitric acid and that formed from the nitration reaction demands the presence of some dehydrating agent. The one found best suited is sulphuric acid. The explosives manufacturer, therefore, is interested in strong sulphuric acid to make nitric acid and as a dehydrating agent. As a result of the war demand there was a tremendous increase of devices for the concentration of the weak acid, resulting from the chamber process, or which is a by-product itself of explosives manufacture. The result is that a great deal of sulphuric acid concentrating equipment was installed in explosives plants, and many hundreds of tons of this material were used to make an excess of nitric over and above any pre-war requirements.

It would be interesting to trace back the effect of the war upon numbers of industries. Take the automobile industry, for instance, and its effect upon the sulphuric acid industry. It is a fact that money made as a result of the stimulus of the war upon manufacturing in the United States has made it possible for a greater percentage of the people to buy automobiles, and these machines demand, of course, more crude oil for fuel and for lubrication. This increased demand along with that of the increased use of oil in the industrial operations for building the cars has resulted in an increased use of the oil resources of the United States. Since sulphuric acid enters largely into the refining of these oils, the acid industry has been called on to measure up to this demand.

If the Southern complete-fertilizer maker had been able to secure potash from some place other than Germany, and southern fertilization had been practised as in normal years, there would have been in the aggregate such a demand for sulphuric acid that there would have been no hope of meeting it. If it had not been for the aid of the Southern fertilizer manufacturer in diverting his acid output from the fertilization of soil to the needs of other industries we would not have had our present industrial activity. The Southern soil, however, cannot weather more than a few seasons of partial fertilization. The increased demand for cotton, both as a result of industrial activity and the manufacture of smokeless power and gun cotton, has forced the Southern cotton grower to wonder what will happen in the coming year if he fertilizes so little as he has for the past two or three years. The three plant foods that are essential in a fertilizer are available potash, available nitrogen and available phosphorus. The only real potash comes from the Stassfurt mines of Germany, although the United States is now producing some low-grade material in Nebraska. We of the United States have the real supply of phosphate rock and in normal times are easily able to make more than enough sulphuric acid to take care of any demand that may be made of its acidulation. With the potash supply from Germany cut off and with the acid supply utilized some other way, the Southern cotton grower has been compelled virtually to do without. This year he is beginning to think that something strenuous should be done, because high prices of cotton and food make fertilization imperative for the reason that a good yield per acre cannot be hoped for unless some potash and acidulated phosphate rock are supplied to the soil. This in turn will stimulate a further intensified production of acid, if such is necessary, and I rather expect this demand for fertilizer will keep on intensely even though the war will have removed the demand for acid for the making of explosives. In other words, after allowing Southern soil to go for two or three years it will probably take more than the normal yearly supply to rehabilitate it.

Sulphuric acid is one of the raw materials entering into the manufacture of most other chemicals, notably nitric acid, hydrochloric acid, salt cake (which is used in the plate-glass business), blue vitriol, green vitriol, almost all organic preparations, artificial leathers, combs, reclaimed rubber, electrical insulators, etc., and one could indefinitely elaborate upon the effect that new industries and the stimulation of increased activities in all lines of business have had on its production. Suffice it to say that it has all resulted in causing an increase of plant capacity so greatly in excess of what apparently can be used after the war is over that some manufacturers are already concerned. Operators will consider it advisable to keep plants running as long as possible before shutting down since it is well known that an idle sulphuric acid plant deteriorates much more rapidly than does one that is running.

Future of the Industry

For the future, I think the general trend will be to relegate acid manufacture to those engaged in the metallurgical industry. I think there will be a gradual decline in the practice of pyrites-burning, and incidentally brimstone, for the express purpose of making sulphuric acid. From an economic point of view this would be probable for the reason that it would seem undesirable for one part of the country to be wasting thousands of tons of available sulphur gas while another part is spending millions of dollars for the purchase of sulphur-bearing material, when a large part of the latter comes from a greater distance than would the acid if it came from the point at which it is being wasted. If we could properly impress the railroads with the advisability of hauling this commodity at rates more comparable with those of other commodities used in equal tonnages and having approximately equivalent values, we might secure a better commercial condition. If this equalization is not practicable, I think there will be a general trend of acid-consuming industries toward the territory at which sulphuric acid may be cheaply produced as a by-product in a manner similar to the trend of industries demanding cheap electrical power to the Niagara Falls district.

Denver, Col

Shale Oil Reserve for Navy.—In the annual report of the Director of the Geological Survey, just made public, attention is called to the creation of two naval oil reserves in Colorado and Utah. The Survey has explored large areas in Colorado and Utah that contain immense deposits of such shales, some of which carry 30 to 50 gallons of oil to the ton. The Colorado reserve created for the Navy contains 45,440 acres, and the one in Utah 86,584 acres.

The Influence of Heat Treatment

On the Electrical and Thermal Resistivity and Thermo-Electric-Potential of Some Steels*

By EDWARD D. CAMPBELL and WILLIAM C. DOWD

THE principal object of the present investigation—which is far from being complete—was to conduct a preliminary study of the correlation of electric and thermal properties of steels in the light of the solution theory if accepted in the full sense of the term.

Although an apparent connection between thermal and electrical conductance in metals had previously been noted by Forbes, it was the systematic work of Wiedeman and Franze in 1854 which demonstrated the relationship was probably a definite one. If this were the case it would be reasonable to expect both electrical and thermal resistivity in metals might be due to the same atomic or molecular mechanism. Although numerous investigators studied the relation existing between electrical and thermal resistivity in metals subsequent to Wiedeman and Franze's publication, it was the exhaustive work of Jaeger and Diesselhorst which demonstrated that the ratio of the electrical to the thermal resistivity is approximately constant for pure metals, but does not hold equally well for impure metals or alloys. In 1897 Schulze[1] measured the thermal and electrical conductivities of five carbon steels and one manganese steel, and showed that the Wiedeman and Franze law did not hold in the case of these metals. It is now generally conceded that the Wiedeman and Franze law—that is, the ratio of the electrical to the thermal resistivity in absolute units—holds quite closely for pure metals, being about 6.5×10^{-10}. It does not, however, hold very closely for impure metals or alloys, although in general any marked change in electrical resistivity is accompanied by a corresponding change in thermal resistivity. During the past twenty years physicists have carried out a great number of experiments in order to determine with increasing degree of accuracy the correlation of electrical and thermal resistivity in metals, with special view to the influence of the temperature at which the measurements were made on this relationship. In almost all this work metals or alloys of metals other than iron were employed. Very few, if any systematic measurements of the thermal resistivity of steel have been made, although the fact that there is a close relationship between the chemical constitution and electrical resistivity of steel has been recognized for more than fifty years, and has served as a basis for many researches.

Although the solution theory of metals, as it is now termed, was first advanced more than a century ago, to the great majority of physicists and metallurgists the term is almost a meaningless phrase, since they still refuse really to accept as a mental concept the essential unity of mechanism of metallic and aqueous solutions. They all recognize and take into account the part played by the solvent as differentiated from that played by the solute in ordinary solutions, and yet, when studying the properties of metallic solutions, many of them refuse to recognize the essential unity of mechanism, and make little or no effort to differentiate between the part played by the solvent and that by the solute. It would seem entirely possible that, if metallic solutions were regarded from exactly the same viewpoint as ordinary solutions, reasonable explanation for many well-known phenomena might be found which cannot be satisfactorily explained in any other way.

In 1915 one of the authors[2] gave experimental evidence to substantiate the conception that total electrical resistivity of steel must be considered as made up of two components—first, that due to the solvent, and, second, that portion due to the carbides in solution; the effect of these latter on the electrical resistivity being proportional to the concentration of the carbides actually in solution. It was there suggested that, as in aqueous solutions, it is the molecules in solution which are capable of reacting with different forms of energy, and consequently the electrical resistivity would be dependent on the molecular concentration of the carbides in solution, since by their reactivity these carbides would cause electrical energy to disappear as such and reappear in the form of heat.

In a later paper[3] the dependence of the electrical resistivity on the concentration of the carbides in solution was confirmed, and it was further shown that if carbides are the only solutes present in noticeable amounts the thermo-electric potential due to dissolved carbides is a function of the concentration. In these same papers it was further shown that electrical conductance is almost entirely through the solvent, while electrical resistivity is only in part due to the solvent, frequently as much as 80 per cent or more of the total resistivity being due to the solutes in solution.

Experimental

The experimental bars used were all machined down to a uniform size of 6 mm. square by 15 cm. in length from stock samples of larger bars furnished by the courtesy of the same companies which have supplied us with bars on our previous work. The composition of the steels used in the present research is given in Table I.

In annealing the steels used, a number of sample bars were usually packed in an electrically heated furnace in such a way as to avoid oxidation, and the temperature raised overnight to that stated as the temperature from which each sample was annealed, after which the furnace was allowed to cool for twenty-four hours and

the large sample bars removed. It was from the sample bars thus annealed that the small experimental bars used for quenching were machined. All temperatures, whether of annealing or quenching, were measured by means of standard platinum-rhodium thermocouples standardized at intervals against the melting point of pure silver taken at 961 deg. C.

The method of hardening the small bars was essentially the same as that employed in this laboratory for some years and described in detail in 1915.[4] The bars to be quenched where suspended in an electrically heated furnace so designed that, no matter how long they were kept in the furnace, there was no oxidation, and carburization, if occurring at all, did not exceed 0.02 per cent. The bars were kept in the heated chamber as a rule one hour, the temperature being measured by a thermocouple placed 2 to 3 mm. from the bars under treatment. The quenching bath was a large volume of ice-water, and, as in our previous work, the time required a bar from the furnace to the quenching bath was a little less than one second, the same amount of time being required to cool the bar from the quenching temperature to below a red heat. Experience in this laboratory has tended to show that bars which are perfectly clean and bright cool somewhat more quickly on quenching than the same sized bars which have been heated in a fused salt bath. These latter, on withdrawing from the heating bath, are covered with a thin film of fused salt which appreciably retards the cooling effect of the water. Enough bars of each kind of steel were quenched to enable the specific resistivity and thermo-electric potential to be measured at the same time. Thermal resistivity was measured on one of these bars after the other measurements had been made. After all the bars had been quenched they were carefully polished and the measurements of specific resistivity, thermo-electromotive force, and thermal resistivity, made with no more delay than was necessary. Numerous experiments in this laboratory have shown that, on account of the instability of the solid solution produced by quenching steel in cold water the specific resistivity and correlated properties will fall off very appreciably even at room temperature within a comparatively short time.

The specific resistances were measured in all cases on bars kept immersed in an oil bath and maintained at a constant temperature of 25 deg. C. The method of determining specific resistance was the same as that heretofore employed, that is, by measuring the fall in potential between knife-edges clamped to the bar 10 cm. apart, while a current of constant density was flowing through the bar.

On account of the rapid change in chemical constitution of hardened steel with increase of temperature it was thought best to make the measurements of specific resistances, thermo-electromotive potential, and thermal resistivity without allowing the temperature of the bars at any time to exceed 35 deg. C. or 40 deg. C. The thermo-electromotive force measured, therefore, was that due to the temperature gradient between 0 deg. C. and 25 deg. C. The method employed was a modification of the one used a year ago and described in detail in one of our previous papers.[5] In the method used in the present work three bars of the same steel and subjected to the same heat treatment were clamped together to form a triple compound bar, to the ends of which were attached, by means of pure iron clamps, the annealed ingot iron leads connecting the ends of the compound bar with the galvanometer by means of which the potential was measured. One end of the compound bar was maintained, as in our previous work, at 0 deg. C. by means of crushed ice, while the other was immersed in the same oil bath as that used for specific resistivities, which was maintained at 25 deg. C. Thus the thermo-electromotive force, measured and expressed in microvolts, represents the difference in thermo-electromotive potential of the steel in question and pure iron over the temperature gradient from 0 deg. C. to 25 deg. C.

As the work herein described is in a sense a preliminary study of the correlation of electrical and thermal resistivities without any attempt to determine the absolute relationship, the thermal resistivities so far determined have all been relative, that of pure ingot iron being taken as unity. It is hoped that later new determinations of thermal resistivities will be made with improvements in the apparatus which will enable such measurements to be made under more favorable conditions, and with a higher degree of precision, so that the results may be reduced to absolute units. The method employed of measuring the relative thermal resistivities herein given was one of the stationary temperature type, the technique of which was developed under the direction of Dr. Carelton V. Kent of the Department of Physics. The detailed description of this method of Dr. Kent is given in the *Physical Review* of 1917.

The method of determining the relative thermal resistivities is briefly as follows: The bars, 6 mm. square and 15 cm. in length, are provided with two holes a little more than 1 mm. in diameter and 4½ mm. in depth, one hole being 5 mm. from the cold end of the bar and the other 10 cm. from the same end. These holes are for the insertion of fine copper-constantan thermocouples, by means of which the difference in temperature between each of the holes and the surrounding space is measured. The holes were filled with paraffin oil before inserting the thermocouples; a better thermal contact being thus obtained between the couple and the steel than when the oil was not used. About 3 cm. of one end of the bar was inserted in a small heating oil by means of which the temperature of the bar at the hot end could be easily raised and maintained constant for any desired length of time. The bar, supported in the heating coil and with thermocouples in position, was inserted into the center of a heavy steel

[4] *Journal of the Iron and Steel Institute*, 1915, No. II, p. 164.

[5] *Journal of the Iron and Steel Institute*, 1916, No. II, p. 268.

cylinder, 20 cm. inside diameter and 40 cm. long, and closed at the inner end with a heavy steel plate. This steel cylinder was, in turn, boxed in, in order to avoid local air currents. The mass of the metal—something more than 20 kilograms—was sufficient to maintain reasonable constancy of temperature throughout the interior during a given experiment. After a bar whose thermal resistivity was to be measured had been inserted into the steel cylinder, a current was turned on through the heating coil until the thermocouple showed a rise of about 10 deg. C. The copper-constantan thermocouples used were made of very fine wires, each being calibrated against a standard thermometer. The couples gave a deflection of about 6 mm. per each degree, so that temperatures could be readily measured to within less than 0.05 deg. C. Since all bars were of the same dimensions, the thermocouple holes were the same distances from the cold end in every case, and the temperature of the higher point of measurement was substantially constant in all cases, the difference in temperature at the cold and hot points of measurement must have been directly dependent upon the thermal resistivities of the bars. Usually from 1½ to 2 hours were required for the system to come to equilibrium. When this had been attained, the ratio of the temperature difference at the hot and cold ends of the bar was calculated. Dr. Kent has shown that the ratio $\frac{\theta_1}{\theta_2} = \cos aL$ in which simplified equation $a = \sqrt{\frac{hp}{cq}}$ where h is the heat lost to the enclosure from 1 sq. cm. of the surface per degree excess temperature, p is the perimeter, c is the conductivity and q is the cross-section of the bar. From mathematical tables giving hyperbolic functions aL may be found from the experimentally determined temperature ratio $\frac{\theta_1}{\theta_2}$. Since we are interested in the reciprocals of the conductivity or the resistivity, the relative resistivities may be easily found from the (aL) as h, p, q, and L the distance between the hot and cold points of measurement, are the same for each bar. The resistivities would, therefore, be directly proportional to the square of the (aL).

The results of the measurements of the specific resistance at 25 deg. C., of the relative thermal resistivity, and of the thermo-electromotive force of the nine steels in the annealed condition, are given in Table II, in which the steels are arranged in order of increasing specific resistance. In this table is also given the specific resistance of the pure ingot iron, which is taken as unity in the determination of relative thermal resistivities and which is also used in opposition to the different steels when determining the thermo-electromotive potential. The small numbers in parentheses following the names of the steels as given in Table II serve to identify the points corresponding with each steel, as shown graphically in Figs. 1 and 2.

TABLE II.—TABLE SHOWING SPECIFIC RESISTANCE RELATIVE THERMAL RESISTIVITY, AND THERMO-ELECTROMOTIVE POTENTIAL OF ANNEALED STEELS.

Steel.	Temperature of Annealing.	Specific Resistance in Microhms.	Relative Thermal Resistivity.	Thermo - Electromotive Potential against Ingot Iron in Microvolts.
	Degree C.			
IN1(1)	778	10.64	1	...
H57 (2)	903	15.28	1.25	116
IN6 (3)	960	15.90	1.35	90
C5 (4)	903	18.05	1.47	128
H1 (5)	700	25.16	1.99	310
M8 (6)	...	25.36	2.03	371
H6 (7)	718	32.24	2.38	232
SN1 (8)	950	41.58	2.84	362
SN3 (9)	985	53.37	3.17	556
MN1 (10)	810	54.25	3.78	334

In Table III are given the corresponding measurements made on the same steels as those given in Table II, but with the steels in the quenched or hardened condition. The steels are again arranged in order of increasing specific resistance, but it will be noted, from the small figures in parentheses following the name of each steel, that the order of arrangement of

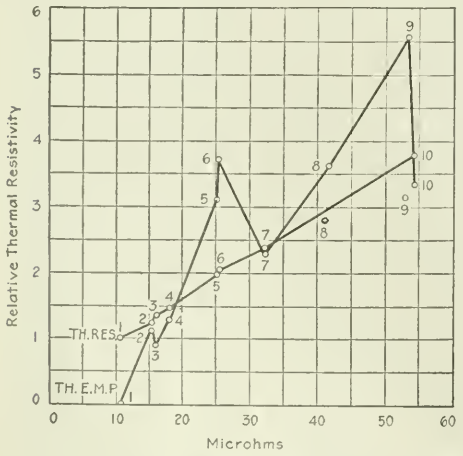

FIG. 1.—THERMAL RESISTIVITY AND THERMO-ELECTROMOTIVE POWER OF ANNEALED STEELS

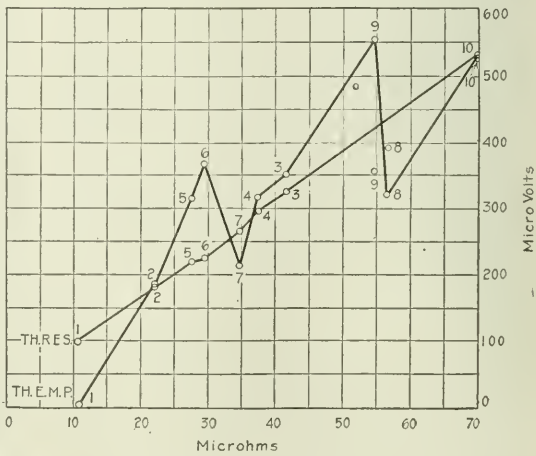

FIG. 2—THERMAL RESISTIVITY AND THERMO-ELECTROMOTIVE POWER OF QUENCHED STEELS

the steels in the hardened condition is quite different from what it was when the steels were annealed.

In order to bring out the correlation of the thermal and electrical resistivities as influenced by chemical constitution and heat treatment, the results of the measurements given in Tables II and III are shown graphically in Figs. 1 and 2. In these the specific resistances in michroms are shown on the abscissæ, while the corresponding relative thermal resistivity and thermo-electromotive potentials are shown on the ordinates. It will be noted that the curve of relative thermal resistivity is approximately a straight line except for two points, 8 and 9, of the steels SN1 and SN3, both of which are high silicon steels, the silicides apparently giving a distinctly higher ratio of electrical to thermal resistivity than do carbides or other solutes.

TABLE III.—TABLE SHOWING SPECIFIC RESISTANCE, RELATIVE THERMAL RESISTIVITY, AND THERMO-ELECTROMOTIVE POTENTIAL OF HARDENED STEELS.

Steel	Temperature of Quenching.	Specific Resistance in Microhms.	Relative Thermal Resistivity.	Thermo-Electromotive Potential against Ingot Iron in Microvolts.
	Degrees C.

MN1 (10)	902	69.80	5.35	534

A study of the data given in Tables II and III, and of the curves shown in Figs. 1 and 2, reveals some interesting relationships, especially if viewed in the light of the solution theory of steel accepted in the full sense of the word. If steel is regarded as made up of a solvent and solutes, we may get an approximate idea of the relationship of that portion of the electrical resistivity due to solutes, to that portion of the thermal resistivity to solutes by subtracting from the total specific resistance of pure iron (10.64), and, from the total relative thermal resistivity, that of pure iron (1.00), and then finding the ratio of the electrical resistivity to the relative thermal resistivity. The ratio of the electrical resistivity to its relative thermal resistivity of pure iron would, of course, be 10.6. If, in the case of the annealed steels, we calculate by the method above just suggested—the ratio of the electrical resistivity to the relative thermal resistivity—we find this varies from 14.3 to 19.7 in the case of SN3, in which the solute is almost entirely silicide. In the case of the hardened steels the ratio of the electrical resistance to the relative thermal resistance due to solutes varies from 13.4 to 17.4, the highest ratio again being due to that of SN3, containing the highest concentration of silicides. These ratios are all noticeably higher than the ratio found in the case of pure iron solvent and confirm what has been known for many years—that the Wiedeman and Franz law does not hold in the case of impure metals or alloys, the electrical resistivity of such metals increasing more rapidly than the thermal resistivity. In all the steels under examination the effect of quenching has been to increase both the electrical and thermal resistivity, the extent of this change being closely connected with the percentage of carbon in the steels. This would be expected, since it is the carbides which precipitate from solution when the steel is annealed and again pass into solid solution when heated above Ac3 just before quenching.

In 1916[4] a hypothesis to account for electrical resistivity in steels was advanced. This hypothesis assumed the essential unity of mechanism of solid solutions and of aqueous solutions, and attributed that portion of the total specific resistivity due to carbides in solution to the transformation of electrical energy into heat, this transformation being due to the fact that it is those molecules in solution that are most reactive toward any form of energy. If heat is assumed to be made up of two forms of motion, one portion being electronic and the rest atomic or molecular motion, we might easily find a reasonable explanation for the correlation between electrical and thermal resistivities based on the solution theory in the full sense of the word. If molecules of solutes in solution are capable of reacting with electrical energy and transforming a portion of this electronic motion into atomic or molecular motion, thus producing electrical resistivity, it would be only reasonable to expect that the same molecules in solution which could transform electronic motion of electricity would also be capable of transforming that portion of heat which exists as electronic motion into atomic or molecular motion. Under this conception we would expect a close relationship between the electrical and thermal resistivities of steel, since they both become dependent upon the chemical constitution.

When carbides are the only solutes present to any considerable extent it was shown in the paper before referred to that there is a parallelism between the thermo-electromotive potential of these carbides and the specific resistance, both being dependent on the concentration of the carbides in solution. From the curve of the thermo-electromotive potential shown in Figs. 1 and 2 it will be evident that the thermo-electromotive potential is dependent upon the chemical composition of the solutes as well as on the concentration. Under the conception of the essential unity of mechanism of metallic and aqueous solutions, the assumption that the thermo-electromotive potential of solutes in solid solution is exactly analogous to the solution tension of electrolytes in aqueous solution would offer a simple explanation for the changes in thermo-electromotive potential due to differences in chemical composition and heat treatment. If a cell be set up with an aqueous solution of a single electrolyte A, the electromotive force of such a cell will be dependent on the chemical composition and concentration of the electrolyte. If a second cell be set up with an electrolyte B, of higher solution tension than A, the electromotive force of the second cell will be higher than that of the first for a given concentration. If a cell be set up with a mixture of these electrolytes, A and B, the electromotive force of such cell will not be additive, but will be intermediate between that of A and B, never reaching as high as when B alone is present. An exactly analogous change will be found in the thermo-electromotive potential of steels when the concentration of the solutes in solution is changed by heat treatment. When the thermo-electromotive potential of the solute

[4] *Journal of the Iron and Steel Institute*, 1916, No. II, p. 8

in solution, other than carbides, is higher than that due to carbides in solution, the thermo-electromotive potential of such steels in the hardened condition tends to be lower than that of the same steel annealed, since in the annealed condition the carbides are very largely precipitated. This is most strikingly illustrated in case of SN1, where we find a distinct drop in thermo-electromotive potential brought about by quenching, although the specific and thermal resistivities are both markedly increased due to the increased concentration of the solutes in solution.

BISHOP, E. S. Assignor to Armour Fertilizer Works.
Treatment of phosphate rock.
U. S. Pat. 1204238, Nov. 7, 1916.
J. Soc. Chem. Ind., 1916, Dec. 30, vol. XXXV, p. 1268.

CHEMICAL PRODUCTS COMPANY.
Process for extracting potassium compounds.
Swedish Pat. 40911, July 5, 1916.
Chem. Abst., 1916, vol. X, p. 2623.

COWLES, A. H., Sewaren, N. J.
Treatment of silicates.
British Pat. 107640, July 4, 1916. (Appl. No. 9418 of 1916.)
J. Soc. Chem. Ind., 1917, Sept. 15, vol. XXXVI, no. 17, p. 962.
Chem. Abst., 1917, vol. XI, no. 21, p. 2946.

ECKEL, E. C., and SPENCER, A. C.
Process of making cement.
U. S. Pats. 1209135, 1209219 and 1209220, Dec. 19, 1916.
J. Soc. Chem. Ind., 1917, Feb. 28, vol. XXXVI, p. 218.
Chem. Abst., 1917, vol. XI, no. 4, p. 390.

ELECTRIC SMELTING AND ALUMINUM COMPANY.
Fertilizer.
Swiss Pat. 71923, March 1, 1916.

ELLIS, C., Montclair, N. J.
Cement and potassium compounds from potassium, feldspar and similar raw materials.
U. S. Pat. 1186522, June 6, 1916.
Chem. Abst., 1916, vol. X, p. 2031.
J. Soc. Chem. Ind., 1916, Aug. 15, vol. XXXV, p. 843.

FIREBAUGH, F. L., Berkeley, Cal.
Sodium and potassium sulfates from leucite, nozelite or nepheline.
U. S. Pat. 1182668, May 9, 1916.
Chem. Abst., 1916, vol. X, p. 1917.
J. Soc. Chem. Ind., 1916, June 30, vol. XXXV, no. 12, p. 690.

FRAZER, J. C. W.; HOLLAND, W. W., and MILLER, E.
Method of treating mineral silicates.
U. S. Pat. 1196734, Aug. 29, 1916.
Chem. Abst., 1916, vol. X, p. 2968.
J. Soc. Chem. Ind., 1916, Oct. 31, vol. XXXV, p. 1059.

HALVORSEN, B. T.
Potassium and aluminum silicates.
Norwegian Pat. 27453, Nov. 27, 1916.

HEWITT, A. C.
Potash becomes a valuable cement mill by-product.
Engng. News, 1916, vol. LXXVI, no. 26, pp. 1222-1226.
Exper. Stat. Record, 1917, vol. XXXVI, p. 625.

HUBER, F. W., and REATH, F. F.
Process for obtaining water-soluble potassium compounds and cement from feldspathic rocks or their derivaties in the manufacture of Portland cement.
U. S. Pat. 1194344, Aug. 8, 1916.
Chem. Abst., 1916, vol. X, p. 2506.
J. Soc. Chem. Ind., 1916, Sept. 30, vol. XXXV, p. 966.

JUNGNER, E. W.
Alkali carbonates; Portland cement.
British Pat. 103290, Dec. 8, 1916.
Chem. Abst., 1917, vol. XI, no. 10, p. 1527.

KOLNITZ, G. F., VON, Charleston, S. C.
Process of producing potash.
U. S. Pat. 1201396, Oct. 17, 1916.

LINDBLAD, A. R., Ludvika, Sweden.
Process for producing potassium or sodium cyanide by mixing feldspar with lime and carbon and treating in the electric furnace.

British Pat. 9183, of 1916 (107426).
(Abst.) *Min. Mag.* (London), 1917, vol. XVII, p. 146.

NEUMANN, B., and DRAISBACH, F.
The opening up of feldspar for the purpose of obtaining potash on a technical scale.
Zeits. angew. Chemie, 1916, vol. 29 I, pp. 313-319; 326-331.
Chem. Abst., 1917, vol. XI, no. 9, p. 1264-65.

PEACOCK, S., Philadelphia. Assignor by mesne assignments to Marden, Orth & Hastings Co., Inc.
Process of extracting alkali from minerals.
U. S. Pat. 1202215, Oct. 24, 1916.
Chem. Abst., 1917, vol. XI, no. 1, p. 89.
J. Soc. Chem. Ind., 1916, Dec. 15, vol. XXXV, p. 1217.

RADMANN, P., Godegard (Sweden).
Method of producing soluble alkaline compounds.
U. S. Pat. 1209201, Dec. 19, 1916.
Chem. Abst., 1917, vol. XI, no. 4, p. 389.

RAVNER, O.
Process for disintegrating feldspars.
British Pat. 102493, Nov. 22, 1916. Norwegian Pat. 27039, June 26, 1916.

Chemical Alliance Succeeds Chemical Committee of Council of National Defense

With the dissolution of the committees of the Council of National Defense, a plan was submitted to the authorities in Washington, whereby the Chemical Alliance, Inc., would take over some of the work of the Committee on Chemicals and its various sub-committees. The Chemical Alliance was originally formed last August to take up certain matters in connection with fertilizers and pyrites importation.

The officers and directors of the Chemical Alliance, Inc., were all members of the Chemical Committee.

Rather than resolve the various sub-committees of the Chemical Committee into separate and distinct trade committees, it seemed advisable to the Chemical Committee at the time of the dissolution of Council of National Defense committees to try and hold its organization intact, and the Chemical Alliance, Inc., seemed to offer the best medium for the accomplishment of this purpose.

Dr. William H. Nichols, chairman of the Committee on Chemicals and president of the Chemical Alliance, Inc., resigned from the presidency of the Alliance, and Horace Bowker, vice-president of the Chemical Alliance, Inc., was elected president. Henry Howard, chairman of the executive committee of the Manufacturing Chemists' Association, was elected vice-president. J. D. Cameron was elected treasurer and secretary pro tem. The directors of the Chemical Alliance, Inc., are as follows: Dr. William H. Nichols, General Chemical Company, New York City; Horace Bowker, American Agricultural and Chemical Company, New York City; E. R. Grasselli, Grasselli Chemical Company, Cleveland, Ohio; J. D. Pennock, Solvay Process Company, Syracuse, N. Y.; William Hamlin Childs, The Barrett Company, New York City; D. W. Jayne, The Barrett Company, New York City; C. H. MacDowell, Armour Fertilizer Works, Chicago, Ill.; C. G. Wilson, Virginia-Carolina Chemical Company, Richmond, Va.; John J. Riker, E. D. & J. J. Riker Company, New York City; F. A. Lidbury, Oldbury Electro-Chemical Company, Niagara Falls, N. Y.; A. D. Ledoux, Pyrites Company, Ltd., New York City; Henry Howard, Merrimac Chemical Company, Boston, Mass., and Edward Mallinckrodt, Jr., Mallinckrodt Chemical Works, St. Louis, Mo.

The offices of the Alliance, Inc., for the present will be 538 Woodward Building, Washington. Telephone, Main 9946.

The sub-committee on fertilizers of the Committee on Chemicals now becomes the committee on fertilizers of the Chemical Alliance, Inc., with offices and telephone number as heretofore.

The Chemical Alliance, Inc., is now not a Government committee, but acts in an advisory capacity to the Government in collecting data, making recommendations, etc. The actual buying of chemicals, explosives, etc., is in charge of Mr. L. L. Summers, whose office is in the Council of National Defense Bldg. This arrangement should work out very satisfactorily to all concerned.

Acidity Determination in Water, Leach Liquors, Mine Waters, Etc.

By James J. Rankin
Assistant Chemist, Research Dept., Phelps Dodge Corporation

THE following method for determining acidity in the presence of sulphates of ferrous and ferric iron, copper, aluminium and manganese is new and is, we believe, much more accurate than the usual titration methods.

The objection to titrating solutions containing ferric iron and copper with Na_2CO_3 is that the ferric iron and copper interfere by giving a more or less indefinite end-point which does not represent the true acidity due to free sulphuric acid. This new method gives a sharp end-point in titrating which corresponds to the true free sulphuric acid present. The presence of aluminium salts in amounts usually found in waters, leach liquors, etc., does not interfere, especially in the presence of ferrous iron.

The method depends on the preliminary reduction of ferric to ferrous iron, and of copper to cuprous iodide, by the addition of potassium iodide, and the subsequent change of the free iodine formed to sodium iodide by the addition of the requisite amount of sodium thiosulphate, after which the ordinary titration with Na_2CO_3 is made.

The equations for the above are as follows:

$$Fe_2(SO_4)_3 + 2KI = K_2SO_4 + 2FeSO_4 + 2I$$
$$CuSO_4 + 2KI = CuI + K_2SO_4 + I$$
$$2I + 2Na_2S_2O_3 = 2NaI + Na_2S_4O_6$$

There is needed for carrying out the method:

1. Potassium iodide C.P. (solution or crystals).

2. Solution of sodium thiosulphate, about 10 per cent or any convenient strength, which need not be standardized.

3. Standard sodium carbonate solution. Strength depends on the percentage of acid in the solution to be titrated, and may be anywhere from $N/5$ to N.

4. Methyl orange.

The following is a description of the details of the method.

A definite volume of the solution to be titrated is measured out. This volume will vary widely with different conditions, being dependent on the acidity of the solution and the quantity of salts present, and may therefore be anywhere from 5 to 500 cc.

Dilute to 250 cc., if the solution has not already this volume, and add an excess of potassium iodide. When copper is present there will of course be a precipitation of cuprous iodide and formation of free iodine.

Add sodium thiosulphate in amount sufficient nearly but not quite to neutralize the free iodine present. Then either filter off cuprous iodide and wash three or four times with cold water or dilute to a definite volume, settle and take an aliquot part for determination.

To the filtrate or aliquot part add a slight excess of sodium thiosulphate as measured by the disappearance of the yellow color due to free iodine. When Cu is not present no filtration is necessary after adding KI, and a slight excess of sodium thiosulphate is then added directly.

The solution will now be colorless or practically so, and after addition of methyl orange may be titrated as usual with standard sodium carbonate solution.

The accuracy of the method is shown by the following experiments:

Ten grams of ferrous ammonium sulphate were dissolved in water, and the ferrous iron oxidized to ferric by the addition of just sufficient potassium permanganate in the presence of a known excess of sulphuric acid. The excess acid was then determined by the above method.

Excess acid actually present = 1.930 gm.
Excess acid actually found = 1.918 gm.

It would have been very difficult to have correctly determined the excess acid in the above solution by the ordinary Na_2CO_3 titration, due to the formation of basic ferric sulphate.

For testing the method on leach liquors a solution was made up carrying ferrous and ferric iron and copper in the amounts usually present in such liquors. The amount of free sulphuric acid present was 0.710 lb. per 1000 gal. The amount found by using the above method was 0.706 lb. per 1000 gal., and by the ordinary Na_2CO_3 method 0.915 lb.

In another test 0.91 lb. per 1000 gal. was actually present, and 0.90 lb. per 1000 gal. was found by the above method. The ordinary Na_2CO_3 titration gave 1.14 lb. per 1000 gal. The new method is accordingly more accurate than the ordinary titration with sodium carbonate.

Another test was made by the new method on a solution containing about 5 per cent each of manganous sulphate, ferrous iron, ferric iron, aluminium sulphate and copper sulphate. The amount of free sulphuric acid actually present by addition to this solution was 3.93 per cent. There was found by the new method 3.97 per cent. This solution would have been very difficult to titrate by the usual sodium carbonate method.

Another test was made to determine the effect of aluminium sulphate. It was found that aluminium sulphate did not appreciably interfere provided considerable ferrous iron was present, as the following one of several tests will show. A solution containing by actual addition 1.29 per cent H_2SO_4 and 0.5 per cent $Al_2(SO_4)_3$ was made. The acid was then determined in 300 cc. of this solution with N Na_2CO_3 and methyl orange. It was found to be 1.45 per cent H_2SO_4, an increase of 0.16 per cent due to the hydrolysis of aluminium sulphate. Another portion of 300 cc. to which 1.3 per cent of ferrous sulphate had been added was now titrated and 1.29 per cent H_2SO_4 was found, the correct amount. This may be explained as follows. At the end-point, the free acid having been neutralized, the ferrous iron begins to oxidize and precipitate, hiding the slightly reddish color of the hydrolyzed aluminium salts. Other sulphates were not found to have this effect.

From the above it seems advisable when titrating solutions containing alumina and little or no iron to add ferrous sulphate before titrating.

The acidity due to the hydrolysis of the aluminium sulphate present can be determined also and a correction factor applied to give the true free acid if necessary.

Chlorides and nitrates have not been found to interfere.

New York, N. Y.

Synopsis of Recent Metallurgical and Chemical Literature

Palmerton Zinc Refractories.—A paper describing the manufacture of spelter vessels, condensers and fire-brick at the Palmerton pottery was presented at the St. Louis meeting of the A. I. M. E. by C. P. FISKE of the New Jersey Zinc Co., Palmerton Works. The bond clay is furnished from St. Louis by the Grand View Fire Clay Co. Several kinds of grog have been used, but calcined flint from the Clearfield district of Pennsylvania has given the best results. Pulverized petroleum coke is also a constituent. The Palmerton pottery is a large and well equipped plant, and can turn out large quantities of retorts, muffles and condensers. The author gives a complete description of their manufacture. The fire-brick made are used principally in the spelter furnace laboratory. As to the qualities desired, the author gives some pertinent points. Theoretically, he says, the perfect vessel should have a maximum heat conductivity, refractoriness, mechanical strength and toughness, and a minimum (or no) porosity and coefficient of expansion. At the same time it should be sufficiently strong when dried to allow handling without undue breakage, and should be chemically inert to the various slags which the gangue in the different types of zinc ores produce. Materials which possess all these desirable qualities are, unfortunately, still to be discovered.

"There are many beds of clay in this country whose refractoriness is amply high. The author has examined and tested many such clays which have exceeded the St. Louis clay in refractoriness, usually to find their shrinkage too high or their toughness too low, or both. Although the combination of St. Louis clay and calcined flint gave the best results of any yet tried, there is still much to be desired. The porosity of this mix, when burned, averages about 6.5 per cent. This figure is found by determining the amount of water the mass will take up in 12 to 15 hr., and where water will penetrate in this time zinc vapors and slag will penetrate during service. This is obviously detrimental to vessel life and spelter practice.

"The purpose of calcined grog in the mix is mainly to lessen the shrinkage of the mass as a whole, by introducing a material which has a much lower shrinkage than that of the bond clay. This in itself produces an undesirable effect, for the bond clay still performs its normal shrinkage during burning, and as it must shrink around the grog particles having a much lower shrinkage, minute cracks are opened up which account largely for the porosity found. A one-material vessel, then, should be more satisfactory, or if cost considerations made two or more materials desirable, they should all have the same shrinkage. As a matter of fact, this latter condition is hardly obtainable, as the drying of the bond clay produces shrinkage which in all probability is partially responsible for this porosity.

"We have at times made vessels containing refractories manufactured under various trade names, but so far without sufficient success to warrant the additional cost of the materials.

"One feature that is probably largely responsible for a certain slowness in developing improvements in vessel manufacture is the difficulty in obtaining conclusive tests. A considerable period of time must necessarily elapse between the first steps in the production of an experimental batch and its final trial in the furnaces, and there are so many factors that may influence the results that it is often difficult to decide just what has been accomplished. Operating difficulties may affect the period of rotting and drying, labor conditions at the spelter furnaces may change, ores may change more or less in their character, and so on almost without limit, as those who have tried probably know. Furthermore, such experiments must be handled with caution, for ill-advised innovations are likely to prove very costly.

"The time required for the manufacture of spelter vessels is a further handicap to the pottery man in determining sources of trouble under ordinary operating conditions. A batch of muffles may at times fail after an unusually short life, or may exhibit certain unusual features which are undesirable, but a search for the cause is usually fruitless. A few months ago some of our muffles showed a peculiar blistering on the outside after firing in the kilns, and there were as many opinions given regarding the cause as there were people qualified to express an opinion. A careful search was made to obtain some clue as to the cause, but without avail, and in a short time the trouble disappeared, leaving us as much in the dark as ever.

"If the perfect material is discovered, pottery men will not be slow in making use of it. In the meantime efforts must be directed toward a judicious selection of the materials obtainable, balancing their good qualities against those which would be detrimental to retort service, together with improvements in their combination and treatment."

Japanese Chemical Notes.—The November, 1917, issue of the *Chemical Technology* gives some data on recent developments in Japan. There are now almost 50 companies making dyestuffs and intermediates, and there is developing considerable competition in some lines. Fuming sulphuric acid is being made on a greatly increased scale. Formic, citric, and oxalic acids are made in considerable quantity, and tartaric acid is also being made. The necessity of making chemical machinery and apparatus is being realized, and has been taken up by one concern. Successful experiments have been made in the production of glycerine from fish waste. The Chemical exhibition was a great success, and was visited by the Emperor, Empress, and others of the nobility who are encouraging the industry.

Leather Conservation.—At the third regular meeting of the New York Section of the American Chemical Society on Dec. 7, Dr. ALLEN ROGERS of Pratt Institute, Brooklyn, discussed the subject of leather conservation. His remarks were as follows:

During the past ten years there has been a slow but constant falling off in hides and skins, which has resulted in a gradual decrease in the production of leather. This shortage in raw stock, with the increased demand for leather products, has thus caused a rise in price of all classes of leather. This country has depended very largely upon European markets for its hides and skins, consequently with this source cut off, due to embargo and non-production, the prices have taken extraordinary bounds. To add to the seriousness of the situation, we find ourselves confronted with a shortage in domestic beef animals, and not having an adequate merchant marine, we are unable to reach the South American markets where large quantities of hides and skins are available.

This condition of affairs is deplorable, especially as the United States leads the world in the production of leather. What cannot be cured, however, must be endured. Although conditions in the leather trade are not so serious as they were a year or so ago, we must use every effort to conserve our resources and patiently await the day when a more efficient marine service will bring the markets of the world to our doors.

As the price of any commodity rises, substitutes are bound to appear. This has been true in the case in hand. Not only have leather substitutes been brought forward, but sources of raw material, formerly waste products, have come to the attention of the tanners, and are being worked up into merchantable leather. Processes also are now being employed which aim to produce a leather having a greater wearing quality than in previous years. Some of the processes are

not new, but at the time they were proposed did not meet with favor by the trade. The reason for the lack of interest was due to the fact that the supply of hides was more plentiful than to-day and tanners did not care to change the process to conform to the new method.

In 1911, the speaker, working in conjunction with another member of this Section, developed a method for producing an indestructible sole leather. This leather was tested out on twenty mail carriers and twenty policemen in New York, using it on the right foot with the best oak sole on the left foot. Two oak soles went through and in most cases they were on the third before the new leather wore out. Shoe manufacturers and tanners did not seem interested at that time, but within the past two years several concerns have started to make the leather and it is now being advertised quite extensively.

The skins of fish have been tanned for many years, but only for fancy articles. To-day, however, shark skins, porpoise, and even gray fish and eel skins, are being converted into very serviceable leather. The shark skins have a very hard grain, but the flesh side lends itself to a finish which bids fair to make it a close competitive of box calf or oil grain. Shark skin leather is very tough and serviceable, which makes it well adapted for children's shoes, especially for boys' knockabouts. Gray fish and eel skins are thin, but can be used for fancy leather and small articles.

For many years the waste shavings and trimmings were burnt under the boiler. To-day, however, they are saved by mixing with pulp and put into leather board for insole work.

A recent invention proposes to work up small trimmings from light leather into a thread or yarn, and then use this yarn in weaving leather fabric. Such fabrics may be used for furniture, automobile leather, rugs, and fancy articles.

The heads or pates of hides formerly went into glue stock; to-day, however, these are being tanned and can be bought in the "Five and Ten" as half-soles and heels at ten cents a pair.

In the production of automobile leather the hide is cut up into sections or splits. As a hide can have only one grain side, the other cuts or splits are treated with a dope finish consisting of gun cotton and castor oil, to which a pigment is added. These splits are then embossed and given the appearance of a full grain.

The manufacture of imitation leather is an American idea and has developed into an enormous industry in recent years. This product consists of a fabric to which is applied a dope finish, the same as on splits. The fabric is then embossed and when used on upholstery is difficult to tell from real leather.

A new process has just been invented for making imitation leather, in which cotton batting takes the place of the fabric. This cotton is worked into shape on a felting machine, and then with a suitable binder is pressed into sheets. These sheets are then given a dope finish and embossed. This process is of special interest as the cost of the finished product is less than the cost of the fabric used in the older process. The strength also is far greater than leather or the other imitation leather.

For a number of years we have known and used rubber soles. Recently, however, several sole-leather substitutes have been placed on the market under various trade names. These sole-leather substitutes depend upon rubber for the binding material, but differ from the rubber sole in that they contain loading material and fibrous matter. Although they do not wear as well as high-grade leather, they do have many points of value which should warrant consideration. Coming as they do when leather is short, they have served to tide us over a very serious situation and will continue to serve as a very timely and satisfactory adjunct to our sole-leather supply.

Recent Metallurgical and Chemical Patents

Fractionating Hydrocarbons.—LEON E. HIRT of Los Angeles, Cal., patents an electric arc apparatus for fractionating hydrocarbon oils. In a copending application Serial No. 41,109, filed July 21, 1915, he has described and claimed a method and apparatus for this same general purpose, in which the oil to be fractionated is subjected to the action of an electric arc within a closed furnace or retort, in which a controllable pressure may be maintained. Hydrogen in some form or other suitable agent is present in the retort, the reaction between the hydrogen and the oil under the heat of the arc being present. The oil vapors thereby produced are conducted away and condensed. The present invention adds some further features to this general method. Referring to Fig. 1, the fractionation takes place in

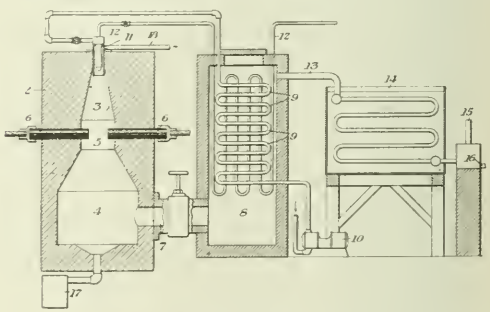

FIG. 1—DIAGRAM OF FRACTIONATING APPARATUS

the furnace or retort chambers designated 3, 4 and 5. Positive pressure of any desired degree can be created within said chamber by regulating the discharge of the vapors to the offtake 7, so as to hold them back within said chamber. In the form of apparatus shown, the ingoing oil is preheated in the chamber 8 to a high degree, since the temperature of the outgoing vapors will be high, depending upon the rate at which oil either atomized or as a vapor is fed. The outgoing temperature can thus be held between 600 and 1500 deg. Fahr, as may be desired. The oil will therefore be discharged into the furnace chamber largely in the form of a vapor and any unvaporized oil will be atomized by the action of the superheated steam passing through the nozzle.

The pump 10 will maintain the oil pressure to the desired intensity, and as the oil and steam pass the arc, the oil is partly broken up and fractionated. The steam introduced with the oil becomes more or less dissociated, the nascent H_2 so formed entering into the reaction with the oils, and by causing the requisite pressure in the furnace chamber, any desired thermochemical compound of the oils can be formed. The O_2 liberated combines with carbon to form CO gas. This is preferable to carbon in the free state, since the latter clogs up the furnace and discolors the condensed fractions. Free chlorine gas may also be introduced with the oil, or oil and steam, to unite with the carbon and form carbon tetrachloride. The latter can be recovered and used as a cleaning compound. Bromine gas may also be added either with or without steam. The halogen gas may be inserted through a pipe, such as indicated at 18. (1,250,879, Dec. 18, 1917.)

Production of Sodium Hydroxide.—CHARLES S. BRADLEY of New York City patents a process for the production of sodium hydroxides and allied products. The process is applicable as an adjunct to the ammonia-soda process. Ammonium chloride and barium carbonate are heated together to form ammonia, carbon dioxide, water and barium chloride. The ammonia, carbon dioxide and water are subjected to a higher temperature and pressure to form ammonium carbonate. This is then subjected to the action of sodium chloride to obtain sodium bicarbonate, regenerating the ammonium chloride. The bicarbonate is reduced to normal carbonate and causticized first with lime, filtered, then causticized with barium hydrate, regenerating barium carbonate for the first reaction with ammonium chloride. (1,249,314, Dec. 11, 1917.)

Lactic Acid.—SIGMOND SAXE of New York City patents a process for the manufacture of lactic acid from vegetable ivory, which is a very hard, ivory-like material used for making buttons and like purposes. Most of it comes from certain tropical American palms (*Phytelephas, sp.*). Waste material from button making and other manufacture can be obtained and used in the process. This is ground to 20 or 30 mesh and hydrolyzed by being boiled with 2 parts of 3 per cent sulphuric acid for six hours and cooled. It is then treated with calcium carbonate and filter pressed, and the liquid is then ready for fermentation. This is done with a lactic organism, capable of producing lactic acid. The fermentation may be conducted in the presence of a base adapted to form lactates, or the fermented mixture may be broken up with sulphuric acid equivalent to the calcium present. (1,249,511, Dec. 11, 1917.)

Potash from Cement Dust.—A process for increasing the solubility of potash in cement-kiln dust is patented by EVALD ANDERSON of Los Angeles (assigned to International Precipitation Co. of Los Angeles, Cal.). Under certain conditions, for example, when coal is used as fuel, causing presence of siliceous matter in the kiln gases, some of the volatilized potash combines with this siliceous matter, forming a difficultly soluble compound. The result is that with potash in this form present in the collected dust, this dust is not rated according to its full potash content as a fertilizer and the recovery of the potash in concentrated form by leaching and evaporation is impracticable, or uneconomical. The main object of the present process is to convert any such comparatively insoluble material in the cement-kiln dust to a comparatively soluble form. This result is effected according to the present invention by subjecting the dust, containing the potash material partly in insoluble form, to the action of steam, preferably at a pressure in excess of atmospheric pressure.

The process is described as follows:

The cement-kiln dust is placed in a suitable container, steam is admitted and the potash containing material is subjected to the action of steam for sufficient time to convert most or all of the potash to water soluble form. In the case of a cement-kiln dust containing six per cent of potash in water soluble form and four per cent in water insoluble form, it was found that an exposure of the same steam at atmospheric pressure (100 deg. C.) is sufficient to convert all but one per cent of the potash to water soluble form. The same effect may be obtained in one hour by the exposure of the cement-kiln dust to steam at two hundred pounds pressure, the rapidity of the action increasing with the pressure and temperature of the steam. After treatment with the steam, the dust may be easily dried, since it absorbs a small percentage of moisture and it may then be used directly as a fertilizer, or it may, if desired, be leached by ordinary means for the purpose of obtaining the potash in a concentrated condition. (1,249,708, Dec. 11, 1917.)

Outlet for Acid Concentrators.—An outlet for acid receptacles is patented by JOEL J. DYE and WM. A. LUCAS of Newark, N. J., and assigned to the Butterworth-Judson Corporation of New York. The patentees state that most acid concentrators have outlets consisting of ordinary pipes with flanges, which are bolted to the wall of the concentrator with interposed gaskets. This method allows hot acid to run over the gaskets and the joints soon leak. The present outlet is designed to do away with this disadvantage. A cross-section of the outlet attached to a concentrator is shown in Fig. 2. The normal acid level is shown at the left.

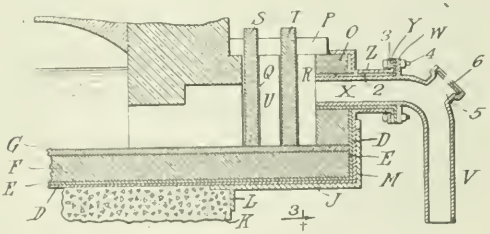

FIG. 2—VERTICAL SECTION OF OUTLET

The tank is constructed of a lead trough *D*, on which is an insulating or packing layer *E* and a course of brickwork *F*, finished with tiling *G*. This floor structure is extended as shown to carry the gates *S* and *T* and the outlet box, which consists of a block *O* of brickwork or other refractory material. A removable cover *P* rests on this block. This serves to prevent the escape of gas. The holes in the cover through which the gates *S* and *T* pass are sealed with sand or other packing material. The outlet pipe *V* is made of acid-proof iron with a flange *W*, located some distance beyond the inlet end of the pipe *X*, which extends into the wall as shown. The flange *W* is bolted to a flange *Y* on the end of a

tubular extension *Z* of the lead casing *D*. There is a seal of the liquid acid between the flame or hot air within the concentrator and the pipe and joints outside, and there is much less expansion of the parts of the joints by heat than where the pipe extends into the concentrator. The temperature of the air within the concentrator may, for example, be about 2000 or 2500 deg. Fahr. while the temperature of the acid is only about 700 deg. (1,249,728, Dec. 11, 1917.)

Wood Distillation.—Apparatus for wood distillation is patented by HARRY O. CHUTE of New York City, and assigned to K. P. McElroy of Washington, D. C. Wood or other vegetable material is destructively distilled in retorts under constant pressure, said pressure being controlled independently of the amount of incondensable gaseous products formed, the gases from the distillation are passed through a temperature-controlled channel to regulate its temperature, and then systematically washed and purified by a countercurrent of tarry or oily bodies, then freed of acetic acid by neutralization with a body of alkaline material maintained at a comparatively high temperature to form an acetate solution and thereafter treated to regain wood spirit. The wood spirit is subsequently purified. The apparatus comprises a retort, means for withdrawing effluent vapors and controlling the pressure, a temperature-regulating device receiving the effluent gases, means for distilling tar, means for systematically scrubbing the effluent gases with the distillate obtained, means for recovering the acetic acid from the purified gases in the form of a concentrated acetate solution, means for thereafter recovering wood spirit, means for purifying said wood spirit, and means for withdrawing incondensable gases, connected to the pressure controlling means. (1,250,282, Dec. 18, 1917.)

Fused Ferric Sulphate.—A process of producing fused ferric sulphate is patented by HERMAN B. KIPPER of Muskegon, Michigan. The raw materials used are sesqui-oxide of iron (iron ore) and niter-cake. The substances are mixed in theoretical proportions and are fused together in any suitable apparatus, at a temperature of 300 to 400 deg. C. If the process is carried out in a rotating drum or cylinder, producer gas is introduced and burned to furnish the heat. The following reaction takes place: $Fe_2O_3 + 6NaHSO_4 = Fe_2(SO_4)_3 + 3Na_2SO_4 + 3H_2O$. The ferric sulphate produced may be mixed with sodium chloride and made into ferric chloride. (1,250,471, Dec. 18, 1917.)

Chlorine Derivatives of Toluol.—The use of ultra-violet light in manufacturing chlorine derivatives of toluol is patented by HARRY D. GIBBS of San Francisco, Cal., and GEORGE A. GEIGER of Washington, D. C. The patent is dedicated to the public. They have found that when the toluol, converted into the gaseous state, is mixed with chlorine gas in definite proportions in the presence of ultra-violet rays, the desired products are produced in greatly increased yields over former processes, and without the production of unfavorable and interfering by-products. They recommend working without a catalyst. The process is especially applicable to the production of benzylchloride, benzolchloride and benzotrichloride. (1,246,739, Nov. 13, 1917.)

Chlorine Substitution Products.—A process for the production of chlorine derivatives of paraffin hydrocarbons is patented by CHARLES BLANC of Akron, Ohio, and assigned to the Goodyear Tire & Rubber Company of Akron. A general description is as follows: Directly into a mass of the employed paraffin hydrocarbon, contained in some suitable reaction chamber, is conducted a stream of chlorine in some measure regulated to conform with the quantity of the hydrocarbon; to facilitate the reaction, particularly in the chlorination of the higher paraffin hydrocarbons, it is advisable to add to the hydrocarbons some halogen carrier. It is essential to this process that the reaction chamber be provided with some means for effectively cooling its contents, and simultaneously exposing said contents to the daylight, or sunlight, or any chemically active artificial light. The contents of the reaction chamber are removed either continuously or intermittently, and any unchanged paraffin hydrocarbon or any undesirable low-chlorinated derivatives of the employed paraffin hydrocarbon, separated from the desired chlorine derivative of the paraffin hydrocarbon by distilling, the unchanged paraffin hydrocarbon or undesirable lower-chlorinated derivatives of the paraffin hydrocarbon being returned to the reaction chamber where they are again submitted to the action of chlorine. The chlorinated paraffin hydrocarbon is removed from the still, washed with some aqueous alkaline solution, separated from the washing solution, and finally, if desired, dried and distilled. (1,248,065, Nov. 27, 1917.)

Potash From Feldspar.—A process for treating potassium-bearing silicate rocks for the recovery of potash is patented by JOHN S. BECKETT of Cranford, N. J., and one-half assigned to P. R. Moses of New York. The process as applied to orthoclase feldspar is as follows:

Orthoclase feldspar is furnaced with coke, limestone and calcium chloride in a copper blast furnace. The calcium chloride is used in sufficient amount to serve as the fluxing agent and to supply the necessary chlorine for forming potassium chloride. The amount of limestone can be varied within rather wide limits, but will in practice be used in such amounts as may be necessary or desirable for giving a melt of low fusion point or for furnishing a melt or sinter of a nature adapted for use for cement or for other purposes. The furnace product can also be thus made use of as a valuable by-product where it is desired to do so. During the furnace operation, the feldspar is decomposed and combines with the limestone and calcium chloride to form a complex silicate, while the chlorine of the calcium chloride combines with the potassium content of the feldspar to form potassium chloride, which escapes with the furnace gases. These highly heated furnace gases are then passed through a waste heat boiler and their heat energy thus recovered in the form of power. The waste gases are then passed through cyclone dust separators where considerable amounts of the potassium chloride are recovered in powder form; after which the waste gases pass to a scrubber in which the remaining potassium chloride is dissolved. The solution thus obtained can be concentrated to crystallization of the potassium chloride, which may then be separated centrifugally or otherwise or the solution can be used directly for the conversion of the potassium chloride into other potassium compounds. The residual melt is drawn off from the furnace to any suitable place of storage or use. When its composition is such that it

is available for use as cement material, it may be granulated by the action of water according to familiar methods. (1,247,619, Nov. 27, 1917.)

Aluminium Alloy.—An aluminium alloy for casting purposes is patented by WILLIAM A. MCADAMS of Bay Shore, N. Y. The ingredients are combined in the proportions of 100 parts by weight of aluminium, seventeen parts by weight of copper, five parts by weight of zinc, one and one-half parts by weight of antimony, and one part by weight of silver. In making the alloy, the antimony is melted in about one quarter of the aluminium at a high heat. The copper is then added and then the silver is added. The heat of the mass is then lowered and the balance of the aluminium is added. The mass is agitated thoroughly and the temperature still further lowered to a dull red and then the zinc is added. The mass is still thoroughly agitated and the scum removed, and the mass may then be cast into ingots. (1,247,977, Nov. 27, 1917.)

Developments in Filtration

AT A MEETING of the New York Section of the Society of Chemical Industry, Oct. 19, 1917, Mr. WALTER L. JORDAN of the Celite Products Company of New York described some very interesting problems in filtration, with particular reference to the use of Filter-Cel as a filter aid.

He divided filtration problems into three classes as follows:

1. Those in which the suspended solids are rigid and either crystalline or amorphous.

2. Those in which the suspended solids are non-rigid bodies, *i.e.*, those approaching the colloidal, although the individual particles may be far greater in size than those properly classed as such.

3. Suspensions containing mixtures of the above classes.

Problems of the first class are the easiest to handle, as it is merely necessary to choose a proper filtering medium, either cloth or screen.

In a few instances precipitates of the second class can be converted into the crystalloidal state either by proper regulation of the precipitation or by subsequent treatment. This should be done wherever possible and thus convert the problem into one under the first class.

Those non-rigid suspended solids which do not lend themselves to crystallization and which have many of the properties and characteristics of colloids (although they may be much larger in size) constitute the most difficult problems in filtration. When one contemplates the difficulties the chemical engineer has to contend with in handling these problems on the large scale, it is easy to understand the aversion to making such separations by filtration and it accounts for the endless attempts that have been made to solve such problems by other means.

Often a problem is rendered more complex by the viscosity of the liquid as in the case of concentrated syrups. In the past gravity filtration has been depended on in coping with this type of problem.

Problems in the third class vary from those in which the rigid particles predominate to those in which practically all the suspended solids are non-rigid.

An example of the third class of problem in which rigid particles predominate is the calcium carbonate precipitate obtained by the carbonation of beet sugar diffusion juice. The precipitated lime carries down albuminous and pectinous bodies through the coagulating effect of liming, heating and carbonating, probably also by adsorption. This precipitate filters readily providing precautions have been taken to bring the calcium carbonate down in a crystalline condition. However, juices from decayed beets offer grave difficulties, because the juices are much higher in organic impurities and especially those of a gelatinous nature, and the normal quantities of lime are not sufficient to render this cake filtrable. Several years ago over 100,000 tons of sugar beets were lost in one State as a result of this condition. The author stated that had supplies of Filter-Cel been available, it would have been possible to have worked these beets up and recovered the sugar.

These two instances in beet sugar carbonation work illustrate the two possible extremes under this class of problem. First the normal beet juice, limed and carbonated, yields a suspension of solids that is readily filtered. In the case of juice from decayed beets the larger percentage of non-rigid solids may make filtration impossible unless much larger quantities of lime or some other filter aid can be incorporated in the cake. The factories burn their own lime and are therefore limited to their normal production of it.

It is always an advantage to coagulate the non-rigid solids as thoroughly as possible. If the impurities are largely albuminous, heat will compact the particles and reduce the volume that they will occupy between the rigid particles present, and the continuity of the pores of the cake will be more nearly maintained. If the coagulation is carried out in the presence of the rigid bodies, the non-rigid will become firmly attached and prevented from being forced through the cake toward the retaining medium.

Some of the diverse problems that have been solved by the application of Filter-Cel as an aid in filtration are as follows:

Vegetable Oils. One of the most interesting applications is in the filtration of linseed oil. This oil is ordinarily filtered warm just as it comes from the hydraulic press. The warm filtered oil on cooling and standing deposits some of the solid fats. By cooling before filtration this after-deposition can be prevented. The addition of about 0.2 per cent of Filter-Cel makes it possible to filter the raw oil at temperatures of 35-40 deg. Fahr. It is probable that a similar procedure would be advantageous in the case of cottonseed and peanut oils, where it is desirable to have an oil of the utmost brilliancy.

Varnishes. Varnishes can be clarified perfectly by filtration in a pressure filter. Usually a thin film of Filter-Cel is first deposited on the cloths from a suspension in clear varnish. The initial film protects the cloths. This is then followed by the cloudy varnish having an additional admixture of ½ to 1 per cent of Filter-Cel.

Lubricating Oils. Used automobile and gas engine lubricating oils contain carbon in a very finely divided state. This carbon has been removed by a Filter-Cel filtration followed by a distillation to remove water, gasoline, etc. It is claimed the revivified oil is superior to the original.

A recent application of Filter-Cel was in the filtra-

tion of wine in a pressure filter. Formerly it was necessary to clarify by means of coagulents such as gelatine, albumen, etc. The process of pressure filtration shortens the time and gives perfect clarification.

Perhaps the most important change in the process of sugar refining in recent years, the author stated, is the adoption of pressure filters of the leaf type in place of the bag filter. This change in method of filtration is made possible by the elimination of the defecation with lime and phosphoric acid. Instead of this a suitable quantity of Filter-Cel is agitated with the liquor just prior to filtration.

Occasionally problems are encountered in which it is not permissible to mix a foreign substance with the precipitate. In such cases, however, it is possible to remove the filter aid in some later process as in the recovery of paraffin by chilling. After the oil has been purged from the paraffin, the latter can be warmed and separated from the Filter-Cel.

The author believes that the use of filtration aids will develop greatly, especially in connection with the more extended use of metallic cloth and screen. Further development will be through the use of higher pressures, thus giving an increased capacity to filtration apparatus.

Flexible Means of Heating Small Space in Industrial Works

The steel-jacketed electric heater-unit shown in the accompanying illustrations has been put to innumerable uses in all kinds of industrial plants. Besides such applications as in crane cabs, valve, pump and meter-

SHOWING AN APPLICATION OF THE C-H SPACE HEATER UNIT IN A METER HOUSE

houses, there have been scores of miscellaneous applications. The ease of conducting electric current to remote corners makes the use of electric heat simpler than any other. The heater-units shown are of 500 watts capacity, and can be connected up in multiple to any a.c. or d.c. circuit where the voltage is not in excess of 250 volts. Only as many as are actually required need be installed, yet additions can be made easily as adding electric lamps. Just as lamps are placed singly or in groups in locations when light is required, so also are these units mounted singly or in groups in locations where heat is required.

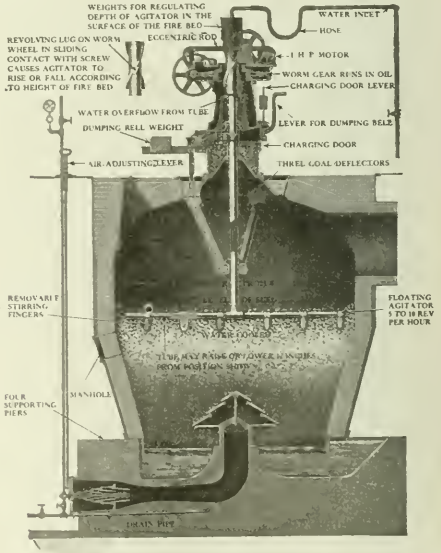
The units are flat like an ordinary meter, the dimensions being 3, 18 in. by 1½ in. by 23¾ in. All parts are enclosed and no porcelain, cement, asbestos or moulded insulation material used. Insulated eyelet holes permit the use of ordinary screws for mounting. Terminal connectors are placed at each end. In mount-

SHOWING CARTON IN WHICH C-H SPACE HEATER UNITS ARE PACKED (10 IN A CARTON)

ing, space is provided between units and between unit and surface on which it is mounted to allow for a good circulation of air. The installation view shows one of these C-H units installed in the gas-valve house in a coke plant. These units are designed and manufactured at the New York works of The Cutler-Hammer Manufacturing Company of Milwaukee.

Floating Agitator for Gas Producers

A NEW development in the gas producer line is being placed on the market by the Chapman Engineering Company of Mt. Vernon, Ohio. Fig. 1 illustrates the construction of this machine. The agitator is in the form of an inverted tee, made of double extra-heavy seamless tubing. It revolves through the surface of the fire-bed at the rate of five revolutions per hour, or more if desired. The cross-arms of the tee are provided with stirring fingers made of high-carbon steel. An inner tube carries cooling water to the end of each finger.



WEIGHTS FOR REGULATING DEPTH OF AGITATOR IN THE SURFACE OF THE FIRE BED
WATER INLET
HOSE
ECCENTRIC ROD
REVOLVING LUG ON WORM WHEEL IN SLIDING CONTACT WITH SCREW CAUSES AGITATOR TO RISE OR FALL ACCORDING TO HEIGHT OF FIRE BED
1 H P MOTOR
WORM GEAR RUNS IN OIL
CHARGING DOOR LEVER
WATER OVERFLOW FROM TUBE
DUMPING BELL WEIGHT
LEVER FOR DUMPING BELL
CHARGING DOOR
AIR ADJUSTING LEVER
THREE GOAL DEFLECTORS
REMOVABLE STIRRING FINGERS
FLOATING AGITATOR 5 TO 10 REV PER HOUR
WATER LEVEL
MANHOLE
FOUR SUPPORTING PIERS
DRAIN PIPE

FIG. 1—INTERIOR VIEW OF GAS PRODUCER WITH FLOATING AGITATOR

The important feature of this agitator is that it automatically accommodates itself to the varying height of the fire-bed. This raising and lowering is accomplished by a special driving-head provided with two large screw-like spiral flanges. These flanges engage in sliding contact with two lugs projecting inwardly from the hub of the driving wheel. Normally the driving wheel and driving-head revolve together, but should the agitator strike an obstruction, or become submerged too deeply in the fire-bed, it automatically "screws up" at once to a point where the forces are again in balance.

If an excessively high fire-bed ever caused the agitator to "float" up to its extreme limit (2 ft.), it would automatically release, thus relieving all strain upon the machinery. The mechanism is driven by a 1 hp. inclosed-type motor.

The agitator is not designed to break up clinkers after they are formed, but to prevent their formation by destroying the blow-holes and hot-spots, which are the primary cause both of clinkers and of poor gas. It is claimed that the frequent stirring of the entire surface of the fire-bed greatly increases the capacity, and improves the quality and uniformity of the gas. Practically all hand-poking is said to be eliminated.

It is stated that the machines can easily be applied to any type of stationary producer already in use. Its makers guarantee that it will increase the capacity 75 per cent, reduce the hand-poking 75 per cent, and maintain a richer and more uniform quality of gas.

The following three analyses represent the average gas made by the agitators in three different steel works. No hand-poking was required, and no objectionable clinkers were made.

	Pittsburgh Gas Coal		Indiana Deep Vein Coal
	Rate per hr lb.		Rate per hr lb.
	1995	1600	1400
CO_2	5.2	5.0	6.6
Ill.	0.1	0.8	.02
O_2	0.1	0.4	0.0
CO	24.1	24.6	19.2
CH_4	2.7	3.5	3.8
H_2	14.0	11.5	13.6
N_2	53.9	54.2	56.6
B. T. U.	143.3	151.0	137.5

These agitators are made in two different forms. First, as a part of a complete producer. Second, separately from the producer proper, to be installed on old style hand-poked uroducers already in use. The agitator is built with or without an automatic coal feeder, as required by local plant conditions.

A New Insulating Material

An insulating material which is said to be fireproof, waterproof, acid proof and electric current proof, composed of chemically treated pulverized waste material which may be molded, stamped or pressed into all special or commercial sizes and shapes, has been developed by Harry A. Dorr and will be made by the Dorrite Insulation Company, 188 Culver Avenue, Jersey City, N. J., after Feb. 1, 1918.

A piece of this insulating material, 3 in. (7.6 cm.) in diameter, ⅛ in. (3.2 mm.) thick, was immersed in water for 70 hours, then subjected to 40,000 volts, and no marks, change in weight or leakage appeared; the same piece was boiled for one hour in cutting oil at 650 deg. Fahr. and stood the same test. A piece 6 in. (15.2 cm.) square and ⅛ in. (3.2 mm.) thick stood a test of 88,000 volts in oil without leakage or breakdown.

Personal

Mr. Robert J. Anderson has resigned his position as chief chemist and metallurgist of the Cleveland Metal Products Co., Cleveland, Ohio, to take effect Feb. 1, 1918.

Mr. C. P. Coleman was elected president of the Worthington Pump & Machinery Corporation at a meeting of the board of directors on Dec. 31.

Mr. A. L. Feild, assistant metallurgist at the Lake Superior station of the U. S. Bureau of Mines, has resigned to enter private employment and is succeeded by P. H. Royster, who has been connected with the iron and steel investigation of the bureau for several years.

Dr. Charles L. Reese, Wilmington, Del., was formally elected presiding officer of the Philadelphia, Pa., section of the American Chemical Society at a recent meeting, to serve in that capacity until December, 1918.

Mr. Forest Rutherford, until recently metallurgist and general superintendent of reduction works for the Copper Queen Consolidated Mining Co. (Phelps-Dodge Corporation) at Douglas, Ariz., is now engaged in consulting metallurgical engineering and has an office at 120 Broadway, New York City.

Dr. Charles E. Vanderkleed, formerly connected with the H. K. Mulford Company, Philadelphia, Pa., has become associated with the Markleed Chemical Company, recently incorporated in New York with a capital of $220,000, and which has acquired the plant of the Waverly Chemical Company at Camden, N. J., now engaging in the manufacture of phenolphthalein, acetyl, salicylic acid, and other synthetics.

Mr. C. H. Vom Baur, well known in the electric steel industry, and formerly with Hamilton & Hansell and other concerns, has opened an office at 30 Church St., New York, where he will engage in consulting work and introduce a furnace of his own design.

Mr. A. P. Watt has opened offices in New York City as metallurgist, where he will specialize on the concentration of ores and the treatment of industrial wastes. His offices are at 52 Vanderbilt Avenue, Room 1903.

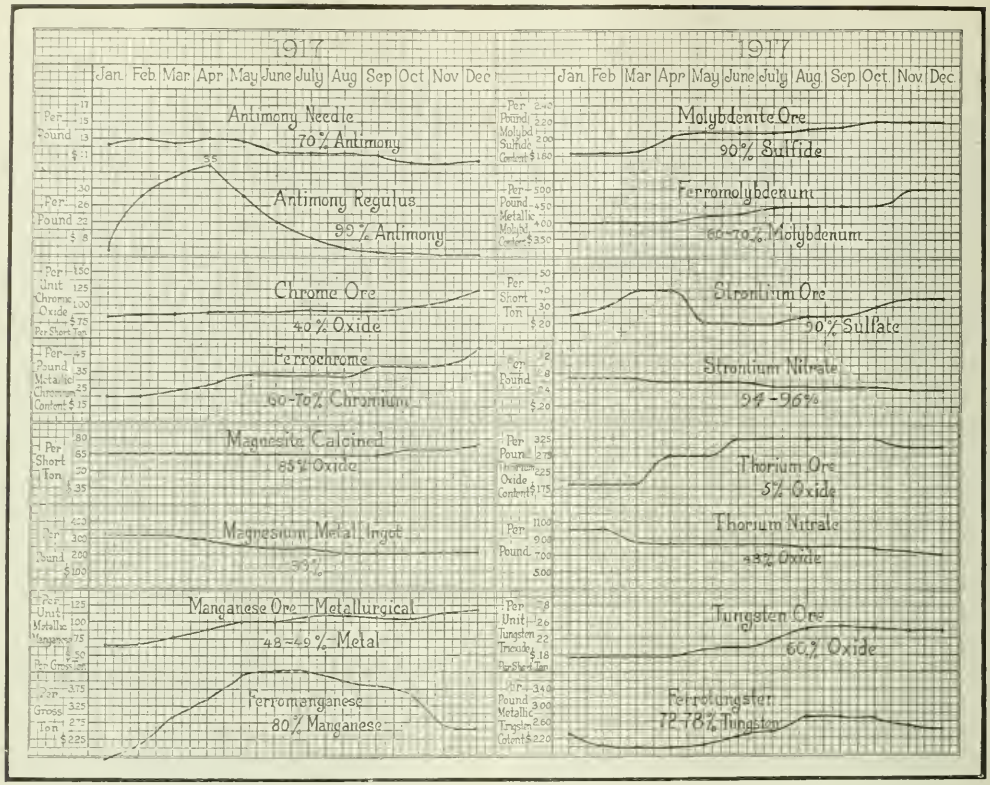
Mr. A. E. Wheeler, consulting engineer for the Union Miniere du Haut Katanga, has recently gone to their head office in London to submit alternative plans for the metallurgical treatment of a large body of oxidized ore occurring on their concession in the Belgian Congo near Elizabethville.

Mr. Bruce C. Yates, assistant superintendent and chief engineer of the Homestake Mining Co., Lead, S. D., has been appointed superintendent to succeed Richard Blackstone, who retired on Jan. 1, 1918. Mr. Yates is a graduate of the University of Nebraska and has been with the Homestake company for the last 20 years.

Obituary

Mr. Silas W. Eccles, vice-president of the American Smelting & Refining Co., passed away at St. Augustine, Fla., on Dec. 31, 1917. Mr. Eccles was also president of the Alaska Steamship Co. and president of the Copper River & Northwestern Railroad. He was born in Washington, Ill., Jan. 3, 1852, and commenced his career in business as a station agent and telegraph operator for the Chicago & Alton Railroad. In 1876 he went to the Denver & Rio Grande Railroad and a year later was appointed general passenger agent of the system.

Prior to becoming connected with the American Smelting & Refining Co. Mr. Eccles was traffic manager of the Oregon Short Line Railroad. In 1900 he became identified with the smelting and refining business, and became a director of the American Smelting & Refining Co. He was also president of the Nevada Northern Railroad and an officer and director of other corporations.



Prices of Some Less Common Products in 1917

The accompanying chart, for which we are indebted to the Foote Mineral Company of Philadelphia, shows the variation in prices in 1917 of several interesting products, including ores, ferroalloys, etc. In addition we include below data on several products also furnished by courtesy of the above company.

Bismuth.—The price remained fairly steady at $3.25 per lb. during the first half of the year. During the last quarter of the present year prices declined still further, due to importations of crude bismuth metal from South America by independents. The present quotations for pure metal range according to quality from $2.65 to $3.00 per pound. The activities of independent South American producers of crude metallic bismuth indicate still further recessions in price for the coming year.

Cerium.—Cerium products remained firm during the year. The two most important products are metallic cerium and cerium oxalate. Ferrocerium was steady at $25.00 per lb. for large contracts. Production is believed to be several thousand pounds per month, and is in the hands of practically only one manufacturer owing to foreign patents.

Palladium.—Owing to the large demand from manufacturers of platinum substitutes the price advanced from $115 in the spring to $125 in the summer and higher figures are now being paid. The bulk of the production is sold far ahead.

Selenium.—Remained firm at $1.20 per lb. during first half of year. During last half an increased demand from the glass trade sent it up to $2.60 to $3.25.

Uranium.—Price remained firm at $50.00 to $60.00 per unit per ton for ore carrying 2 per cent U_3O_8. Black uranium oxide remained firm at $3.25 per lb., 96 per cent U_3O_8.

Vanadium.—Ferrovanadium ranged from $2.75 to $3.00 per lb. of metal contained for 30 to 35 per cent material. During the last quarter this price advanced to as high as $7.50, owing to large Government demands.

Current Market Reports

The Iron and Steel Market

Announcement on behalf of the President, Dec. 28, that iron and steel prices as set would be continued to March 31, has not resulted in any change in the general situation as to activity. The market remains very dull all along the line, a reflection doubtless of general conditions. There is still a large volume of contract business to be carried out, and under present conditions, with prices set, with Government priority being given on a great deal of material, and with the rate of production uncertain, the natural tendency is not to buy for deliveries far ahead. A part of the dullness of the past few weeks is doubtless to be attributed to the year-end adjustments, taking of inventory, making up tax estimates, etc., all particularly complicated this year, and having to be accomplished with reduced office forces, so that the usual tendency of the iron and steel market to be dull at this season is naturally accentuated.

Price Revision Later

The trade, both sellers and buyers, seems to have tacitly assumed that the proviso in the Washington announcement, that contracts made involving delivery after March 31 must carry a clause providing for readjustment of prices against any prices that may be set later by a Government agency, means that probably prices will be re-

duced by March 31 or shortly thereafter. The only question is whether the Washington authorities are looking forward to a voluntary agreement by the iron and steel producers for lower prices, or are depending upon prospects that the Pomerene iron and steel price fixing bill will be enacted. It is understood that the bill is to have precedence over nearly everything else in the two houses.

The contention that the present set prices are necessary by reason of the cost of production has not been particularly successful. The costs of some producers are extremely high, but they represent only a small percentage of the total production, and in many cases high costs are directly traceable to there being contracts for raw materials at higher than the set prices or to irregular operation due to congested traffic conditions. The Federal Trade Commission desires to correct the first drawback to economical production by having Congress give the Executive the authority to cancel such contracts, while the latter difficulty is to be corrected by producing better transportation conditions. That would be a small thing for Government operation of the railroads to accomplish, for the total amount of transportation the iron and steel industry has lacked, between its recent rate of operation and operation at capacity, is only a fraction of 1 per cent of the total freight moving facilities of the country, measured in ton-miles.

Pig Iron Production

For several weeks the blast furnaces tributary to the Connellsville coke region have operated at an average of 80 to 90 per cent of capacity in the case of the merchant stacks and at 70 to 85 per cent in the case of the steel works furnaces. Shipments of Connellsville coke have averaged barely 300,000 net tons a week, against 350,000 tons a week during the first nine or ten months of 1917 and 421,000 tons a week in 1916. The furnaces do not need as much of this coke as in 1916, by reason of many by-product ovens having since been completed. The coke region maintains it could have shipped much more coke if transportation had been available. So far as can be seen, if transportation were provided 75,000 tons more coke per week could be furnished, and that would mean, say, 75,000 tons more pig iron a week. With intermittent operation through frequent banking, and through coke being held in ovens over 72 hours waiting cars and getting overburned, the average coke consumption at many blast furnaces has risen by hundreds of pounds per ton of iron. Now 75,000 tons more pig iron would mean correspondingly more steel and the market might take on quite a different aspect if there were this increased production, for there is no evidence that consumers generally have been greatly incommoded by the reduced deliveries of the past few weeks. The increased output of iron and steel might prove quite formidable, whereas the additional transportation required is inconsequential. The 75,000 tons of coke a week would represent roughly about 10,000,000 ton-miles of freight per week, and last summer at any rate the railroads of the United States were producing more than 8,000,000,000 ton-miles of freight movement per week. Thus one-eighth of 1 per cent more transportation applied to the iron and steel industry would probably produce a very striking alteration in the relation between demand and supply.

Contracts in Force

The finished steel industry is operating largely on old contracts. In bar, shapes and plates the deliveries, apart from those on Government orders, are chiefly against contracts made prior to last May, since which time there has been little buying of these products except for early deliveries, or against Government requirements. In pipe, wire products and sheets the deliveries are more against sales made lately for shorter periods. The interest of the mills at this time is chiefly in converting the present contract obligations into definite orders and shipments. In most cases there is no definite sales policy, the idea being that that is a matter for the future, and the market is really drifting. In a few weeks more, particularly if transportation conditions improve, the future of the steel market, as to prices and demand, should have at least a little light thrown upon it.

War Requirements

There is much confusion of thought as to the war requirements in steel, this being caused by the natural tendency to ascribe nearly all steel consumption to war requirements, as nearly all the consuming industries are more or less helpful in prosecuting the war. This is theoretically a correct viewpoint, but practically it settles nothing, for it is not the production of steel but the use of steel that helps to win the war, and these consuming industries have their limitations, which, of course, are purely physical. Those who use steel as a result of being given Government orders, as munition manufacturers, shipbuilders and the like, are in one category; those who use steel to produce oil, coal, farm implements and the like are in another category. To the former price may be no object. To the latter it is an object.

There are certainly possibilities of steel in many forms becoming decidedly more plentiful and indeed of having occasion to seek its market. Leadership in point of scarcity has for nearly two years been given to plates, yet the market in the past fortnight has disclosed rather free offerings of plates, of certain specifications, by half a dozen or more mills, and when that occurs in plates there is room for much inference as to what may occur in the next few months as to steel products generally.

Non-Ferrous Metal Market

Monday, Jan. 7.—The tin market is dull and prices are considerably lower, in spite of the great scarcity of supplies. Nothing of special interest has happened in the copper and zinc markets. Lead has been advanced by the Trust.

Copper.—The prices remain at 23.50 for producers and 24.67½ for jobbers as fixed by the Government. There is apparently enough copper available for all purposes at present, but considerable concern is felt over the coal and railroad situation. In London standard is quoted at £110 and electrolytic at £125. The demand for copper in munitions making is expected to increase rapidly.

Tin.—The situation is no better and were it not for the fact that there seems to be but little consuming demand a very serious situation would be the result. Two weeks ago Straits tin sold up to 85 cents, but it has now declined to a nominal quotation of 67 cents, following a sensational decline in the London market from £302½ to £269. The London market has recovered, however, and spot Straits is quoted now at £281. Total deliveries in December were 4683 tons, with stocks on hand at the end of December of only about 500 tons. Spot tin of any kind is hard to obtain at present. Future Chinese No. 1 is quoted at 62.00 cents.

Lead.—The trust price of lead was advanced on Jan. 3 to 6.50 cents New York basis. The outside price is 6.75 to 7.00 cents. Following a dull period, a large demand has sprung up from consumers. Government purchases have been settled on the average St. Louis prices, while New York prices were lower.

Spelter.—This market continues dull, with a slightly better demand for Grades A and B for Government work. Grade B is now 10.25 cents. Prime Western is held at 7.75 cents.

Antimony.—The antimony market continues dull, with 14.50 cents quoted.

Tungsten.—Tungsten ore remains at $24.00 for high-grade wolframite and $26.00 for scheelite. It is difficult to move material on account of the railroad congestion.

Molybdenite.—Price remains at $2.25 to $2.30 per lb., with a fair demand.

Quicksilver.—Supplies are scarce and the market has advanced to $130-$135 per flask for California material.

Other Metals

Aluminium, lb.	.36–.38
Bismuth, lb.	3.00–3.50
Cadmium, lb.	1.50
Nickel, electrolytic, lb.	.55
Silver, oz.	.89⅝
Platinum, oz.	105.00
Palladium, oz.	130.00–135.00

Chemical Market

Coal Tar Products.—Conditions in this market have been quiet of late. The requisitioning by the government of several of the important items has tended to a certain extent to restrict operations. The scarcity of material has also contributed toward the conditions obtaining.

Benzol.—Offerings are liberally made, but the buying demand is much below normal. Consumers of large quantities who ordinarily cover for the year on contract are backward about doing so and low prices therefore hold sway.

Phenol.—Governmental requirements are receiving first consideration and offerings are light, with a slight advance in price.

Naphthalene.—Not much interest is displayed by either buyers or sellers at present, spot material is scarce and forward positions are fractionally advanced in price.

Toluol.—The government has seized practically the whole production, and there is none obtainable on the open market. A few drums pass now and then at fancy figures.

Aniline Oil.—A slightly improved demand, together with a scarcity of the necessary acids, has caused a firmer position and a slight advance in price.

Salicylic Acid.—The production of late has been heavy and a few factors in the market were absorbing the output until recently, when their requirements were filled, with the result that prices have declined.

Beta Naphthol.—Was in better demand and spot stocks of the technical grade are in light supply, but prices thus far are unchanged. The sublimed material is in better supply and the demand is light.

Dinitrophenol.—Offerings are liberal with the demand light and prices unchanged.

Para-amidophenol.—A heavy production with a falling off in the demand has caused prices to decline.

Ortho-Toluidine.—The toluol situation has caused a scarcity of this material, and only a few dealers are quoting, with prices slightly higher.

Para Toluidine.—Is in better supply, although there are only a few dealers offering, with prices unchanged.

Anthracene.—Is practically off the market, several inquiries having failed to locate material quantities.

HEAVY CHEMICALS.—The movement in chemicals during the past two weeks has been of a minor character and prices, as is usual toward the close of the year, have shown a tendency to ease off. There is reported to have been more inquiries coming in during the first week of the new year, and this is generally taken as an indication of activity soon to develop.

Caustic Soda.—There has been no real buying for consuming accounts since our last report. The short interest which has developed during the period since Oct. 1 is reporting much difficulty in having bills of lading accepted and these bills are being rejected on the slightest technicality. As a consequence there has been a decided speculative interest shown in certain positions such as December bills of lading for 25-ton cars. Buyers have been willing to pay concessions to cover in exact conformity with contracts to avoid disputes. Spot positions have receded to 6.40 and 6.50. Over the year quotations vary from 6.35 to 6.60, according to seller. The usual probability of nondelivery attaches to the low quotations.

Soda Ash.—Owing to the lack of export licenses, bags have firmed up and are scarce, while barrels are more plentiful and easier. The movement has been entirely speculative, however. December bills of 25-ton cars have been mostly in demand to fill in contracts. These commanded 3.05 to 3.10 as we write, while barrels in contrast were available at 3c. to 3.05c. From the works bags were obtainable at 2.90c. to 3c.; barrels at 3c. to 3.05c.

Acids.—As there is seemingly no sulphuric acid other than the 66-degree concentration and but limited trading in that, there is little that can be stated regarding the market. Sixty-six degree brimstone acid has sold at $75 to $80, drums included, with a few spot offerings from time to time at $43, drums extra. *Oleum* has sold at $65 and $75, and $80 is now asked. *Muriatic acid* as a result of government buying has become so scarce that the 18-degree material is now practically the only test available and sellers are asking 4c. for June-December delivery. *Nitric acid* has not been so active, and 42-degree material is available at 9c. to 10c. *Phosphoric acid* has eased off owing to the lack of demand and the 48/52 per cent is now available at 7c. to 7¼c.

Chlorate of Potash.—Manufacturers established the price of 40c. shortly before the new year covering 1918 business and shortly announced that in some instances this price had been advanced to 42½c. However, the outside market has not responded and sales of December chlorate were closed the first week of the year at 39c. It will be recalled that all during 1917 the outside market was lower than the contract price.

Bichromates.—Spot soda and potash has been somewhat firmer. This is principally due to the railroad situation. For soda the 1918 price is 16½ to 17c., but the contracts contain so many war clauses that the buyer really does not know how much he will pay for the product before he consumes it.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JAN. 7, 1918

Acetic anhydride	lb.	1.80 — 1.90
Acetone, drums	lb.	Nominal

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

THE ALLIANCE IRON & STEEL CORPORATION, New York. Capital, $75,000. To engage in the manufacture of iron and steel products. Incorporators: H. F. Holly, H. C. Gable and G. D. Zahm, 261 Broadway.

O. H. ANDERSON & COMPANY, New York. Capital, $50,000. To operate a plant for the manufacture of paper and paper specialties. Incorporators: O. H. Anderson, C. C. and E. Mandel, 163 St. Nicholas Avenue.

THE ANIMAL BY-PRODUCTS COMPANY, Miami, Fla. Capital, $30,000. To engage in the manufacture of fertilizer. Incorporators: W. A. Henderson and L. C. Haughey, Miami.

THE GEORGE BANTA PAPER COMPANY, Menasha, Wis. Capital, $30,000. To operate a plant for the manufacture of finished paper. Incorporators: George Banta, Sr.; George Banta, Jr., and R. E. Thickens, Menasha.

THE BEST FOUNDRY COMPANY, Brooklyn, N. Y. Nominal capital, $9,000. To operate a local foundry. Incorporators: J. Danziger, U. S. Adler and L. B. Louis, 35 Nassau Street, New York.

BLACKMAN & FINK, New York. Capital, $25,000. To engage in the manufacture of chemicals and allied products. Incorporators: M. Fink and J. and E. Blackman, 66 East Ninety-ninth Street.

THE CENTRAL IRON & METAL COMPANY, Paterson, N. J. Capital, $25,000. To engage in the production of iron, steel and other metal products. Incorporators: B. and A. and J. Jacobs, and H. Hurwitz. Paterson.

THE CLEVELAND BRASS PRODUCTS COMPANY, Cleveland Heights, Ohio. Capital, $3,000,000. To manufacture and fabricate brass, zinc, copper, etc. Incorporators: C. R. Hamilton, Edward C. Decust, Cleveland Heights; Mark W. Cole and M. S. Pollock, Dover, Del.

THE COMMERCIAL CYLINDER COMPANY, Hackensack, N. J. Capital, $800,000. To manufacture gas, oils, etc. Incorporators: Cornelius Cole, Hackensack; A. R. Oakley, Pearl River, N. Y.; and Paul E. Britsch, Brooklyn, N. Y.

DECK BROTHERS, Buffalo, N. Y. Capital, $35,000. To operate a local foundry and machine shop. Incorporators: A. G. Bartholomew, B. L. Lempenau and A. S. Perrers, Buffalo.

THE DUNLAP PAPER COMPANY, Batavia, N. Y. Capital, $15,000. To engage in the manufacture of paper. Incorporators: M. Clark, S. Dunlap and A. Hawkins, Batavia.

THE EAST DEERING FOUNDRY COMPANY, Portland, Me. Capital, $10,000. To engage in a general foundry business. Incorporators: George R. Thomas, Charles E. Noyes, Joseph G. Noyes and A. F. Thomas, all of Portland.

THE EUREKA ANILINE PRODUCTS CORPORATION, New York. Capital, $10,000. To engage in the manufacture of dyestuffs and allied products. Incorporators: H. Suhr, H. P. Velte and R. Bennett, 503 West 169th St.

THE FABRICATED STEEL PRODUCTS CORPORATION, New York. Capital, $150,000. To engage in the manufacture of steel products. Incorporators: W. E. I. Lambrecht, H. Lindemann and W. Arnold, 322 Tenth Avenue.

THE GLIDDEN COMPANY, Cleveland, Ohio. Capital, $10,000. To manufacture paints, etc. Incorporators: Howard T. Clark, C. C. Owens, Ellis B. Diehm, Paul J. Bickel and Sterling Newell, Cleveland.

GOLDSMITH BROTHERS SMELTING & REFINING COMPANY, Atlanta, Ga. Capital, $10,000. To engage in the smelting and refining of metals. Incorporators: Frank H. Leslie, Atlanta; Lowell A. Lawson and Leon L. Lewis, both of Chicago, Ill.

THE GOOD CHANCE MINING COMPANY, Miami, Okla. Capital, $30 000. To mine for lead and zinc. Incorporators: George Ostrander, Miami; R. W. Eastman and H. H. Sherman, Alva, Okla.

THE GREAT FINDS OIL & REFINING COMPANY, Wilmington, Del. Capital, $50,000. To drill for oil and gas and refine same.

THE GREAT SCOTT MINING COMPANY, Kansas City, Mo. Capital, $25,000. To engage in the mining of lead and zinc. Incorporators: E. A. MacBride, A. B. Munsey and J. J. Johnston, Kansas City.

THE HELLER & MERZ COMPANY, Newark, N. J. Capital, $1,500,000. To engage in the manufacture of chemicals, dyes, etc. Incorporators: A. Foshay, A. G. Thanum and Arthur Williams, all of New York.

THE HOFFMAN-PERRY IRON & STEEL COMPANY, Youngstown, Ohio. Capital, $75,000. To deal in iron and steel products. Incorporators: Louis Hoffman, Frank C. Hoffman, Frank W. Perry, M. J. Sussman and G. F. Hammond, Youngstown.

THE HOME PULP & PAPER MILLS COMPANY, Mobile, Ala. Capital, $100,000. To manufacture paper and paper products. Incorporators: F. B. Armstrong, J. S. Armstrong and M. McGowan, all of Mobile.

THE LAMBERT CHEMICAL COMPANY, St. Louis, Mo. Capital, $20,000. To manufacture chemicals and allied products. Incorporators: W. and A. W. Lambert and A. R. Deacon, St. Louis.

S. B. LEONARDI & COMPANY, New York. Capital, $10,000. To manufacture chemicals and kindred products. Incorporators: B. and A. B. and S. B. Leonardi, New Rochelle.

THE MANVILLE MANUFACTURING CORPORATION, New York. Capital, $300,000. To manufacture chemical fire extinguishers. Incorporators: S. Bennett, Jr.; R. Sherman and R. W. Evans, 14 Wall Street.

THE MERCHANTS FERTILIZER & PHOSPHATE COMPANY, Charleston, S. C. Capital, $25,000. To manufacture fertilizer and phosphate. Incorporators: E. H. Pringle, Jr., B. G. Pringle, F. E. Barron and A. F. Pringle, Charleston.

THE MERRIMAC VENEER COMPANY, Byram, Miss. Capital, $50,000. To manufacture paints, varnishes, etc. Incorporators: Frank and Robert Morrison and Thomas McCase.

THE METLSKIN COMPANY, Rochester, N. Y. Capital, $10,000. To manufacture chemicals. Incorporators: A. E. Van Houten, C. H. and G. B. Miller, Rochester.

THE NATIONAL REDUCTION COMPANY, Dover, Del. Capital, $1,100,000. To manufacture charcoal, tar and turpentine from wood, etc. Incorporators: Guy V. Ferguson, James H. Kirkpatrick, New York; Earle L. Woodward, Great Kills, Staten Island, N. Y.

THE NITRO CHEMICAL CORPORATION, Wilmington, Del. Capital, $2,000,000. To manufacture explosives of all kinds.

THE PEOPLES MUTUAL LEAD & ZINC COMPANY, Muhall, Okla. Capital, $1,000,000. To mine for lead and zinc. Incorporators: G. M. and W. C. Wolfe, and Thurman Ellison, Muhall.

THE PURITAN STEEL COMPANY, INC., New York. Capital, $50,000. To manufacture iron and steel. Incorporators: Herman Brasch, William J. Miller and T. T. Teichberg, New York.

THE RICHVALE FURNACE COMPANY, New York. Capital, $1,000,000. To manufacture furnaces. Incorporators: Samuel B. Howard, G. V. Reilly and A. W. Britton 65 Cedar Street.

THE SEQUOYAH OIL REFINING COMPANY, Dallas, Tex. Capital, $50,000. To engage in the production of oil and the refining of same.

THE STAR CHEMICAL MANUFACTURING COMPANY, Los Angeles, Cal. Capital, $10,000. To manufacture chemicals and allied products. Incorporators: Hyman Feder, K. M. Bonoff, D. A. Monheit and E. V Rosenkranz, all of Los Angeles.

THE STAYWITE COVERING COMPANY, Queens, N. Y. Capital, $10,000. To manufacture paints, enamels, lacquers and celluloid surface coating. Incorporators: H. Harjes, J. F. Hicks and H. J. Crofield, 560 Rogers Avenue, Brooklyn.

THE STEPHEN ENGINEERING COMPANY, Dover, Del. Capital, $500,000. To manufacture furnaces and appliances.

THE TRUMAN M. SMITH MACHINE COMPANY, Grand Rapids, Mich. Capital, $60,000. To engage in the manufacture of foundry products. Incorporators: T. M. Smith, Jr.; L. P. Rice and Gerald McCoy, Grand Rapids.

THE VOSS ALCOHOL EXPORT CORPORATION, New York. Capital, $50,000. To manufacture alcohol, etc. Incorporators: H. W. Voss, G. A. Moore, 27 William Street; R. E. Voss, 123 West Ninety-fifth Street, New York.

Construction and Operation

Alabama

BIRMINGHAM. — The Sloss-Sheffield Steel & Iron Company is planning for the early operation of its Hattie Ensley Furnace No. 2, under daily capacity of about 300 tons. Repairs made at the furnace have cost over $300,000.

BIRMINGHAM.—The National Cast Iron Pipe Company, which recently filed notice of an increase in its capitalization from $350,000 to $500,000, is planning for the immediate erection of additions to its plant to increase the present capacity. Included in the work will be a new steel and cement foundry building, about 50 x 200 ft., which will be equipped with cranes, cupolas and facing and drilling machines for flange pipe.

HOLLINS.—The Parkdale Graphite Products Company, recently incorporated with a capital of $100,000, has completed its organization arrangements and is planning for the immediate development of 200 acres of land. It is said the output of the plant will be approximately ten tons of graphite each hour. Headquarters of the company are at Talladega. R. G. Nickles is president and manager; A. H. Sawyer, Hollins, is construction engineer.

Arkansas

HARRISON.—The Kreuger-Mills Mining Company, recently organized by W. O. Kreuger and E. H. Mills, of Springfield, Mo., has acquired 300 acres of land in connection with a large plant and is planning for immediate operations for the production of lead and zinc. The company will also make improvements in the works to cost about $20,000.

California

BAKERSFIELD. — The Standard Oil Company is planning for the construction of a new machine shop at its plant at McKittrick.

BERKELEY.—Peet Brothers, manufacturers of soaps, are planning for the construction of a large new factory at their local works. Head offices of the company are at Kansas City, Mo.

MARTINEZ.—The Atlas Powder Company has acquired a large tract of land, consisting of 206 acres, just north of its plant, and it is reported that the property will be used for extensive additions to its present works. The property was secured at a price of $50,000.

SAN DIEGO.—The United States Shipbuilding Company has recently inaugurated active work for the construction of its proposed shipbuilding plant on property recently acquired on the tidelands, San Diego Bay. The company is said to be negotiating with the Emergency Fleet Corporation for the construction of ten steel vessels, with total capacity of about 90,000 tons, at the new plant. Adam Weckler is manager.

WEST OAKLAND.—The Southern Pacific Railroad Company is planning for extensive improvements and alterations in its creosoting plant to cost about $350,000. The plant will be completely modernized, and with extensions, will cover about 25 acres of land. The works will have a creosoting capacity of about 3,000 000 ft. of lumber per year. J. A. Barlow is assistant chief engineer.

Connecticut

STAMFORD. — The John Davenport Foundry Company is having plans prepared for the construction of a new two-story concrete factory building, about 90 x 300 ft., to be erected on Davenport Place. The estimated cost of the structure is $90,000. Henry Marvin, Main Street, Stamford, is architect.

WEST HAVEN.—The Consolidated Rendering Company, 69 North Market Street, Boston, Mass., is making rapid progress in the construction of a new one-story local plant, about 18 x 220 ft. U. G. Carmichael, 902 Chapel Street, New Haven, is the contractor.

Georgia

ATLANTA.—Plans have been completed for the erection of the proposed new plant of the Doss Rubber & Tube Company at Fort McPherson. The works will be about 55 x 142 ft., one-story, of stone and brick, and will have floor space of approximately 18,000 sq. ft. When completed the factory will have a capacity of 500 inner tubes and 500 casings daily. The Pittman Construction Company, Atlanta, is the contractor.

Illinois

BLUE ISLAND.—The American Wire Fabrics Company, 208 South LaSalle Street, Chicago, is having plans prepared for the construction of a large new local plant to cost about $200,000. Frank D. Chase, 122 South Michigan Avenue, Chicago, is the architect and engineer.

CHICAGO.—Rapid progress is being made by the Chicago Bearing Metal Company, 2234 West Forty-third Street, in the construction of a new one-story addition, about 102 x 226 ft., to its bearing metal plant, to cost $15,000.

CHICAGO.—The Hughes Electric Heating Company, Waller Avenue and Taylor Street, has taken out a building permit for the construction of a new one-story plant, about 87 x 250 ft., to be used for the manufacture of electric heaters.

EAST ALTON.—Construction has been commenced by the Consolidated Chemical Products Company on a new one and two-story factory, about 75 x 235 ft., to cost $80,000.

EAST ST. LOUIS.—The Durbin Automatic Train Connector Company, Pontiac Building, has awarded a contract to the F. Woerman Construction Company, Century Building, St. Louis, Mo., for the erection of a new foundry building on Bond Avenue, to cost $25,000.

Indiana

FT. WAYNE.—The Supreme Motor Corporation, Union Building, Cleveland, Ohio, is having revised plans prepared for the construction of a new one-story local plant, about 100 x 400 ft., to cost $300,000.

FT. WAYNE.—Rapid progress is being made by the General Electric Company in the construction of a new factory building at its local works. Contract has been awarded to the Bedford Stone & Construction Company, Fletcher Trust Building, Indianapolis, Ind.

HAMMOND.—The Standard Steel Car Company, Frick Building, Pittsburgh, Pa., has completed plans for the erection of a new one-story addition to its local machine shop, about 250 x 800 ft., of brick and steel construction, to cost $250,000. Contract has been awarded to the McClintic-Marshall Construction Company, Oliver Building, Pittsburgh.

Kansas

WICHITA.—The Benjamin J. Sibbitt Iron Company has acquired property on Santa Fe and First Streets, about 132 x 290 ft., for a consideration of $16,000, and is having plans prepared for the erection of a new one-story brick foundry, which will be operated in addition to its present structural works.

Louisiana

NEW ORLEANS.—The New Orleans Refining Company has acquired a large tract of land on the old Sarpy plantation, near New Orleans, as a site for the construction of a new oil refinery.

NEW ORLEANS.—The Gasoline Corporation has recently acquired a site of land having a frontage of about 1000 ft. on the Mississippi River and about 50 acres deep, and is said to be planning for the construction of a large new plant for the refining of gasoline.

Maryland

CURTIS BAY.—The Associated Chemical Company, manufacturer of fertilizer, etc., is planning for the construction of new additions and extensive improvements in its local plant. Headquarters of the company are at Hagerstown.

BALTIMORE. — The Bartlett-Hayward Company has awarded a contract to Morrow Brothers, Fidelity Building, Baltimore, for the construction of a new two-story brick, steel and concrete foundry at Scott and McHenry Streets.

BALTIMORE.—The Hess Steel Corporation is planning for extensive improvements and additions to its plant to provide for increased capacity, to include the erection of a new mill-construction plant building, containing about 19,000 sq. ft. of floor space, and a new administration building. The new equipment will consist of electric melting furnaces, cranes, pouring equipment, etc., for the production of electric-furnace alloy steel.

Michigan

GRAND RAPIDS. — The Tannewitz Works, 315-31 Front Street, have had plans prepared for the construction of a new two-story brick and steel addition, about 96 x 96 ft., to its factory and machine shop. Pierre Lindhout, National City Bank Building, Grand Rapids, is the architect.

LANSING.—The Lansing Chemical Company has awarded a contract for the erection of two one-story additions to its chemical manufacturing plant, about 50 x 50 and 50 x 100 ft., respectively, to William T. Britten, 821 West Ottawa Street, Lansing.

Minnesota

MINNEAPOLIS.—A new one-story brick foundry addition to its plant, about 195 x 297 ft., will be erected by the Gas Traction Foundry Company, 1907 Fourth Street. The structure will cost about $70,000. Plans are being prepared by W. L. Alban, Endicott Building, St. Paul.

Missouri

KANSAS CITY.—Contract has been awarded by the Oxygen Gas Company, Traders Building, for the construction of its proposed new one-story and basement factory, about 44 x 120 ft., to cost $60,000. A. G. Harper, Indiana Avenue, is the contractor.

ST. LOUIS.—The Wagner Electric Company, 6100 Plymouth Avenue, has awarded a contract for the construction of a new one-story plant, about 130 x 512 ft., to cost $60,000. The new works will be devoted to the manufacture of ammunition. W. M. Sutherland Building & Contracting Company, Syndicate Trust Building, St. Louis, has the contract for erection.

ST. LOUIS.—The American Manufacturing Company, 1026 South Eleventh Street, is having plans prepared for the construction of a new one-story brick and concrete power plant, about 60 x 80 ft., at East St. Louis, Ill., to cost $40,000. Klipstein & Rathman, Chemical Building, St. Louis, are the architects.

Nebraska

OMAHA.—The Sprague Tire & Rubber Company, Twentieth and Harney Streets, is having plans prepared for the erection of a new three-story and basement tire and rubber plant on Izard Street, between Eighteenth and Nineteenth Streets, to cost about $200,000. George B. Prinz, 1033 Omaha National Bank Building, is architect.

New Jersey

CAMDEN.—The New York Shipbuilding Corporation has awarded a contract to the J. S. Rogers Company, Moorestown, for the construction of a one-story addition to its plant, about 50 x 130 ft., to be used as a galvanizing plant. The structure will cost $10,000.

RIDGEFIELD PARK. — The British-American Chemical Company, 52 Vanderbilt Avenue, New York, has acquired the plant and property of the Tennessee Copper Company, Ridgefield Park, and is planning for the construction of several new additions, the entire works to be devoted to the manufacture of chemicals.

JERSEY CITY.—Fire, on Dec. 21, destroyed a portion of the plant of the George H. Segal Company, Inc., 139-141 Logan Avenue, manufacturer of chemicals, with loss estimated at approximately $40,000.

NEWARK.—Fire, on Dec. 22, destroyed the plant of the Newark Rubber Company, 192 Emmet Street, with loss estimated at $50,000, of which $30,000 is for machinery.

PERTH AMBOY.—The Roessler & Hasslacher Chemical Company is planning for the immediate construction of a new one-story addition to its plant, about 50 x 165 ft.

DUNELLEN.—The Crescent Color & Chemical Works, 1735 West Front Street, is having plans prepared for the construction of a new two-story addition to its plant, about 70 x 80 ft., to cost $10,000.

SOUTH RIVER.—The Para Products Company, manufacturer of rubber goods, is planning for the rebuilding of its plant recently destroyed by fire. The new works will be about 100 x 200 ft.

NEWARK.—Colgate & Co., manufacturers of soaps and perfumes, have announced the acquisition of a tract of twenty acres at Point Newark Terminal on which a large plant will be built and where many new hands will be employed. No definite steps will be taken as to the building of this plant until the end of the war. This property is not far from the Submarine Boat Corporation's shipyards, and is along the same shore line of the American Synthetic Dye Works, and other large industries. It is in the neighborhood of the new locations on the Passaic and Hackensack rivers recently acquired by the Ford Motor Company, the United States Steel Corporation, and the Niles-Bement Pond Company.

New York

COLLEGE POINT, L. I. — The American Hard Rubber Company, 11 Mercer Street, New York, has had plans prepared for extensive improvements and alterations in its local plant. Alexander Macintosh, 55 Bible House, New York, is the architect.

BROOKLYN.—The E. W. Bliss Company, Adams & Plymouth Streets, manufacturer of munitions, will build a new seven-story plant, about 200 x 380 ft., on property recently acquired on Fifty-third Street, near First Avenue, South Brooklyn. When completed the new plant will represent an investment of approximately $1,400,000.

BROOKLYN. — Preliminary plans are being prepared by Louis Leavitt, 454 Driggs Avenue, for the construction of a new three-story and basement varnish factory, about 100 x 125 ft., at Driggs Avenue and North Eleventh Street, to cost about $70,000. William A. Giesen, 104 West Forty-second Street, New York, is the architect.

BROOKLYN.—The National Lead Company, 111 Broadway, New York, has had plans prepared for the construction of a new three-story reinforced concrete plant on Gold Street, from Marshall Street to Hudson Avenue. William Higginson, 21 Park Row, New York, is the architect.

ALBANY.—Fire recently destroyed a portion of the iron foundry of George H. Thatcher, Pleasant Street, which was engaged upon Government work. It is said that the destroyed section will be immediately rebuilt.

TROY.—The Rensselaer Polytechnic Institute, Broadway, will build a new four and five-story addition to its chemical laboratory, about 43 x 112 ft., and plans for the structure, which is estimated to cost $120,000, are being prepared by Lawlor & Hasse, 69 Wall Street, New York.

BUFFALO.—Plans have been prepared by the American Car & Foundry Company, 380 Babcock Street, for the construction of a new paint shop at its works to cost about $12,500.

BUFFALO.—The Pratt & Lambert Company, Tonawanda Street, manufacturer of paints, varnishes, etc., has taken out a building permit for the construction of a large addition to its plant to cost $30,000.

North Carolina

MT. AIRY.—The Tar Heel Manganese Company, recently incorporated with a capital of $100,000, is planning for the immediate development of 80 acres of land for initial operations and increasing the capacity during the coming spring. W. P. Sinclair, Welch, W. Va., is treasurer.

MURPHY.—The Appalachian Iron & Mining Company, with plants at Blue Ridge and Ellijay, Ga., is planning for the installation of new machinery at its works, including portable compressors, tripod machine drills, gasoline locomotives, etc., for the mining of iron ore. S. Long of Etowah, Tenn., is president.

Ohio

AKRON — The Kelly-Springfield Tire Company, Kelly Avenue, has awarded a contract for the construction of a new two-story addition to its plant, about 48 x 87 ft., to cost $10,000. W. A. Franklin Sons Company, 327 Cuyahoga Falls Avenue, has the contract for erection.

AKRON.—The B. F. Goodrich Rubber Company, manufacturer of rubber tires, etc., will build a new one-story mill room addition to its plant, about 112 x 150 ft., to cost $20,000. Contract for erection has been awarded.

CINCINNATI.—The D. T. Williams Valve Company, Spring Grove Avenue and Township Street, has taken over the plant and property of the Queen City Brass & Iron Company, Spring Grove Avenue and Garrard Street, Camp Washington, for a consideration of $300,000. The Williams company is planning for the immediate operation of the plant in addition to its present works, to provide for the steadily increasing demands for its product.

BARBERTON.—The Portage Rubber Company, Barberton, is making rapid progress in the erection of its new local plant. The works are estimated to cost $75,000.

CLEVELAND.—The National Carbon Company has acquired property comprising about five city lots adjoining its carbon extraction plant at Scranton, Pa., and is planning for the construction of a large addition to provide for increased capacity.

COKE OTTO.—Plans are being prepared for extensive improvements and additions to the plant of the Hamilton Furnace Company, near Hamilton, to include the erection of a car dumper to cost about $175,000; a new water softening plant, $30,000, and a new ore bridge to cost $150,000. The new improvements, when completed, will represent an expenditure of about $500,000.

DAYTON.—Contract has been awarded by the Wright Aeroplane Company to Frank Hill Smith, Inc., 120 Broadway, New York, for the construction of a new one-story addition to its plant, about 300 x 1000 ft., to cost $100,000.

MANSFIELD.—A new one-story factory building will be constructed by the Phoenix Electric Company, Olivesburg Road, to provide for increased capacity. The structure, which will be about 50 x 100 ft., will cost $10,000. Contract has been awarded to Simon Small & Son, Bird Building, Mansfield.

MARIETTA.—Plans have been prepared by the Leidecker Tool Company, 119 Second Street, for the erection of a new one-story plant, about 100 x 175 ft., concrete and steel construction, at Westview, near Marietta. Foster Leidecker is general manager.

McDONALD.—The Carnegie Steel Company has awarded a contract to the Youngstown Foundry & Machine Company, Youngstown, for the installation of a new 10-in. hoop mill at its local works.

URBANA.—The Central Glass Company, which has taken over the plant of the Eagle Glass Company, has completed improvements and alterations at the works, costing about $100,000, and is planning to inaugurate operations at an early date.

Oklahoma

MIAMI.—The Miami Zinc & Lead Syndicate, recently incorporated with a capital of $5,000,000, has acquired the porperty of the St. Louis Mining & Smelting Company, including 1400 acres of mineral lands, and is said to be planning for the construction of several large mills and a smelter plant.

Pennsylvania

BURNHAM.—The puddling furnaces of the Logan Iron & Steel Company were closed temporarily on Dec. 20, due to coal shortage.

CATASAUQUA.—The Crane Iron Works has banked one of its stacks for lack of coke. As soon as conditions improve the plant will be reopened.

ERIE.—The American Sterilizer Company, Twelfth and Plum Streets, is making rapid progress in the construction of the new one-story brick addition to its plant, 50 x 70 ft., to cost $10,000. The Stader Conrath Construction Company, Palace Hardware Building, Erie, is the contractor.

PUNXSUTAWNEY.—Fire recently destroyed the plant of the Eldred Window Glass Company with loss estimated at $200,000. The company is planning for the immediate reconstruction of the plant.

READING.—The Reading Iron Company has completed improvements, including the relining of its Keystone blast furnace, and is planning to place the stack in operation at an early date.

MOOSIC.—Fire on Dec. 19, caused by an explosion, destroyed a portion of the plant of the duPont Powder Company, with loss estimated at $25,000.

WILLIAMSPORT. — The Valley Iron Works, 209 West Street, has awarded a contract for the construction of a new two-story plant, about 45 x 75 ft., to cost $15,000. J. V. Bennett & Company, 309 West Third Street, Williamsport, is the contractor.

Tennessee

HARRIMAN.—Joseph and William Baker have acquired the plant and property of the Harriman Mine Car Manufacturing Company and are planning for the construction of several new additions and extensive improvements to increase the present capacity.

NASHVILLE.—Reports from Nashville, Tenn., are to the effect that E. I. duPont de Nemours & Co. is planning to erect a big plant in Big Bend, near Nashville, it being stated that the plant will employ about 4000 persons. Whether this plant will manufacture dyestuffs or explosives has not been definitely stated. According to the Nashville Banner, Daniel Caufield, real estate purchasing agent for the duPonts, has definitely stated that the company would employ 4000 people at a plant to be located in Big Bend.

Texas

RUSK.—The Texas Steel Company, Beaumont, has acquired the Rusk foundry property for a consideration of $112,500, including iron furnace, pipe foundry, etc., and is planning for extensive improvements and the reopening of the blast furnace, to have a capacity of 120 tons of iron daily.

BROWNSVILLE.—The LaBlanca Sugar Company, recently organized with a capital of $500,000, has acquired the sugar factory of the LaDonna Sugar Company, near Donna, with 4000 acres of land adjoining the plant in Hidalgo County; also 8000 acres of land in Cameron County, and is planning for extensive improvements in the plant acquired to cost about $50,000. J. G. McDowell, Pittsburgh, Pa., is president.

Virginia

ST. PAUL.—The Clinch Valley Chemical Company, recently incorporated with a capital of $5,000,000, has had plans prepared for the construction of a large by-product plant. It is anticipated that the plant will be in operation early in the spring.

West Virginia

CHARLESTON.—The Powhatan Brass & Iron Works has awarded a contract to Glaize & Brother, Winchester, Va., for the construction of a new one-story foundry at its plant.

Wisconsin

MADISON.—The Four Lakes Ordnance Company, 2305 Waunesa Street, is making rapid progress in the construction of its new one-story plant, about 150 x 590 ft., which will be devoted to the manufacture of guns. It is estimated that the plant, when completed, will cost $1,000,000. The Austin Company, Euclid Avenue, Cleveland, Ohio, is the contractor.

MILWAUKEE.—The Milwaukee Paper Box Company, manufacturer of paper boxes and kindred products, is having preliminary plans prepared for the construction of a new plant to cost about $150,000, to provide for increased capacity.

MILWAUKEE.—The Liberty Foundry Company, 967 Grand Boulevard, has commenced the erection of a new one-story foundry, about 65 x 120 ft., on Watertown Plank Road, to cost $15,000. J. D. Morrison, 625 Sixty-ninth Avenue, West Allis, is the contractor.

MILWAUKEE.—The Gerlinger Steel Casting Company, specializing in the production of steel castings, has commenced the construction of two new additions to its plant, each 40 x 50 ft., to provide for increased capacity. John J. Gauser, West Allis, is the contractor.

Manufacturers' Catalogs

THE WILSON WELDER & METALS COMPANY, INC., New York City, has issued catalog No. 2, describing the Wilson system and giving considerable general information of value in welding.

THE AMERICAN HARD RUBBER COMPANY, 11 Mercer Street, New York City, has issued a very attractive catalog describing its line of acid pumps, piping and utensils.

Other New Publications

CALIFORNIA MINERAL PRODUCTION FOR 1916, with county maps. Bulletin No. 74 of the California State Mining Bureau, Ferry Building, San Francisco. Walter W. Bradley, author.

MATERIALS FOR THE HOUSEHOLD.—Circular No. 70 of the Bureau of Standards. Issued Dec. 5, 1917. Price 25 cents. From Superintendent of Documents, Government Printing Office, Washington, D. C. Contains valuable information for manufacturers of products used in the household.

Trade Notes

N. B. PAYNE has opened an office in the Havemeyer Building, 25 Church Street, New York, as an electric crane specialist, supplying new and used traveling cranes. Mr. Payne was formerly associated with Manning, Maxwell & Moore, Inc., New York.

THE ECONOMY ENGINEERING COMPANY of Chicago, manufacturer of tierling machinery and portable elevators, has established its own New York office at 85 Murray Street. The company was formerly represented in New York by the Standard Scale & Supply Company.

GRASSELLI CHEMICAL COMPANY TO INCREASE CAPITAL.—There will be a special meeting of the stockholders of the Grasselli Chemical Company on January 24, at which the stockholders will vote on a proposition to increase the company's authorized capital from $20,000,000 to $50,000,000. The plan is understood to include an increase of the authorized issue of preferred shares from $5,000,000 to $15,000,000, and the common stock from its present issue of $15,000,000 to $35,000,000.

STANDARDIZATION OF DYESTUFFS.—Upward of 200 company representatives and individuals from all parts of the country have expressed their intention of attending the two-day meeting which is to be held in Rumford Hall of the Chemists' Club, No. 50 East Forty-first Street, on January 22 and 23 to further the movement which has been initiated to standardize American dyestuffs and aniline colors. Practically all of the leading manufacturers and dealers have approved the movement and promised to attend. H. Gardner McKerrow, manager of the textile department of E. F. Drew & Co., who has handled all of the details of the proposed meeting, will open the convention as temporary chairman.

In addition to standardization of dyestuffs and colors, the meeting will give consideration to several other matters of prime importance to the dye and dyestuffs industry. Among the latter may be mentioned the question of tariffs, arbitration of disputes, and protection of contracts. Numerous other matters which properly come within the function of a trade association will be discussed, as it is stated that the initial idea is to form a "National Dyestuffs Association," which will fill the same relation to the industry as do various cotton and woolen and other trade associations to their industries.

NEW SWEDISH DYE COMPANY.—The A. B. Kemisk Industrie, a new company, has taken over the undertaking carried on for a year and a half under the same title by A. V. Holson, for the production of coal-tar dyes. The new company proposes to extend the works so as to be able also to produce chemical materials of importance to Swedish industries, particularly for the manufacture of munitions. It is believed that it will be possible to begin the manufacture next autumn of about 100 different dyes. The company will have the largest laboratory in Sweden and will employ a staff of from 25 to 30 chemists, whose numbers will be gradually increased. The share capital has been fixed at 5,000,000 kr. ($1,330,000). It is stated that the works have already produced a number of dyes which in every respect appear to compare well with German products. The Swedish requirements amount to 10,000 tons per annum, and to those attention will first be paid. As raw materials to be used are principally mentioned benzol from the Swedish gasworks, acids, bases, salts, etc., which for the most part are produced in the country, which also is able to provide most of the machinery and plant required. The Superfosfat Fabriks A. B., of Stockholm, which is the principal Swedish chemical industry company, has an interest in the undertaking.

OTHER NEW SWEDISH INDUSTRIES.—Scarcity of fats of every description has caused the creation of new industries in all European nations for the production of fats of every kind from sources hitherto considered unpromising. In Malmo, Sweden, a new corporation has been organized named the Aktiebolaget Feddindustri, with a capital of $1,340,000 to produce fats from bones and any other material that yields fat good for soap and other industrial purposes.

A corporation named the Höganäs-Billesholm Aktiebolaget is investigating an invention for producing aluminium out of the clay found in the vicinity of Höganäs, Sweden. A new factory will probably be built near Trollhättan, which will be able to utilize economically about 6000 hp. from the large waterfalls at that place.

One of the industries developed by the war is the Svenska Elektron, which was organized at the end of 1915 with a capital fo $53,600. The capital is now being increased to $268,000 to carry on the additional business that is constantly developing in the silver and other metal specialties made by the company.

City Gas and Modern Warfare

THE exigencies of war are likely to familiarize every domestic user of gas with one phase of our great chemical industry and its relation to modern combat. We refer to the recovery of toluol from city gas and its conversion into trinitrotoluol, TNT, the high-explosive of modern warfare. The shortage in this commodity, which has been recovered largely from by-product coke-oven gas, will be brought home to every user of city gas in this country before the campaign for its production is over. Gas consumers thus become vitally interested in the production of explosives, and in the end it is likely that they will profit by changes in gas standards which are otherwise desirable and which war is only hastening.

Two different standards exist for determining gas quality. Almost every city has adopted one, and some have both. There is the candle-power standard, which is now considered antiquated, being a relic of the days before the incandescent mantle was known. Opposed to this is the more modern and scientific heating-value standard which grades gas in terms of British thermal units. Now toluol and benzol are important factors in both the heating and lighting values of city gas. Hence the removal of these hydrocarbons, or particularly toluol, will reduce both the lighting and heating values below the standards prescribed in various cities. This has necessitated a revision of the standards already in effect by city ordinance, and in some cases has involved the consent of public service commissions.

From estimates made by the U. S. Bureau of Standards as to the influence of toluol recovery on gas quality it appears that candlepower is more seriously affected than heating-value by the removal of toluol. This suggests the elimination of the candlepower standard altogether and the substitution of a heating-value requirement; and since there are other reasons for abandoning the older standard in favor of the newer, the effect of the war is to hasten the adoption of an otherwise desirable practice.

Thus are peaceful pursuits modified by the requirements of war. Hitherto city gas has been just a convenient form of fuel to be had for the turning of a valve; suddenly it becomes an important source of a war necessity. That we have not always recovered toluol from city gas and thereby been prepared for the present emergency is due to economic conditions and not to lack of knowledge or ability. Like many other by-product industries which we have left to our European neighbors, toluol recovery has not appealed to us. It served us best in the gas where it was originally formed, and there was no good reason for taking it out. Technical industry is replete with similar instances.

The Dyestuff Association

THE Dyestuff Association of America has been duly organized and we wish it well. When those interested in the manufacture and sale of anything meet to consider the general welfare it is usual that preliminary negotiations have more to do with who shall guide than with who shall contribute. In this respect the participating manufacturers of dyestuffs and intermediates felt that their investments and interests required that only manufacturers should be members, while dealers might be associate members without voting power but with single representatives on leading committees. This was a wise provision, because in the dyestuff industry, while manufacturing and selling very properly go hand in hand, the economic problems have to do with manufacturing. The art of selling dyes and giving the proper service with sales is difficult and it has been to many a profitable undertaking, but it sinks into unimportance when compared with a well co-ordinated, native manufacturing industry.

Before the great war, dyestuffs were principally made in Germany and sold here, originally through German agencies; and even down to 1914 the selling was in good part under German control. It was a business replete with German traditions, being at once efficient and rotten. The bribery of dyers was an established custom. "They all did it," said an old dealer, "and the only difference in this connection between Americans and Germans who engaged in the practice was that the Americans knew it was wrong and the Germans didn't." The nomenclature of products still has the ear-marks of the undesirable sort of German *Kultur*. It is unconscionably ugly and devoid of all enlightenment or fancy except in so far as it was designed to deceive.

The association will now have to find itself. Able men with high ideals are earnestly interested. Reforms in pre-war selling practices are urgently needed. just as is the development in manufacturing. The tariff should be amended by the elimination of the joker that was inserted into the bill at the last moment whereby alizarine and indigo products were excepted from the specific duty; but when that is accomplished let us hope that the association will devote itself in the maximum to research and development and in the minimum to profits by acts of Congress. The start is auspicious.

Tendencies in Copper Milling

IT HAS been observed that there are prevailing styles in ore-dressing which change from time to time in accordance with ideas evolved through research and experiment. These changes may be abrupt, but are more often gradual and usually there is a transition period during which tendencies can be observed which later become established custom. Copper milling has been particularly responsive to progressive suggestions, and for that reason has been one of the most interesting branches of ore treatment.

The principal tendency observed in copper milling for some years past has been to eliminate stage-crushing and to devise flow-sheets producing no coarse concentrates. In this manner preliminary crushing by rolls followed by regrinding of jig tailings in edge-running mills is apparently being supplanted by a finer original reduction by disc crushers and tube or ball-mills. One notices a tendency for the trommel to be replaced by the impact or shaking screen. Mill men are also beginning to appreciate the necessity of adequate settling capacity to catch the last portions of mineral from spent water, and huge tanks for settling, thickening and de-watering are quite common.

Flotation is used on every hand, either as the main concentrating device, or as an expedient to recover mineral formerly lost in slimes and tailings. The beauty of simplicity seems to have been attained in some of the latest installations, where the flow-sheet consists of the four steps: crush, float, thicken, filter. This wonderful process has enabled the mill-man to produce a tailing extraordinarily low in value, the majority of these losses being of oxidized particles which will not float. He is therefore turning his attention to the task of recovering these last modicums of value—indeed, the outstanding problem in milling practice today seems to be to devise some economical and practicable method for handling ores which contain a mixture of copper oxides and sulphides. This problem is usually attacked by hydrometallurgy; sulphidizing flotation (as practiced at Hurley and elsewhere) may come under this head, since the oxide probably goes first into solution, even superficially, before being precipitated as a sulphide.

These tendencies in the mill are responsible for the increasingly large quantity of fine concentrates sent to the smelter, shipments often consisting of large tonnages of a sticky filter-cake containing upwards of 15 per cent of water. Many revisions in smelting equipment are due to this cause. Particularly in the roasting department, pan feeders are necessary to deliver a constant quantity of this wet material to the furnace. The large Herreshoff or Wedge furnace, or a modification of these styles, is now being installed almost exclusively, and in some cases supplanting the smaller McDougall roasters. The top of these furnaces is utilized as a preliminary drying hearth, while auxiliary heat is usually necessary to complete the roast. Separate coal-fired fire-boxes, powdered-fuel burners, and oil torches are each successfully used for this purpose. The ample drop-hole area afforded by the larger furnaces is also essential to prevent huge dusting losses when handling the extremely fine materials now so prevalent.

The Fuel Order

WE SHALL comment but briefly on the now famous fuel order of Dr. Garfield. It has received attention, respectful and otherwise, at the hands of editors throughout the country and has generally been condemned. We should not lose sight of the fact, however, that the great majority of the critics have not been handicapped by any personal knowledge of the underlying causes and have, therefore, been able to discuss the subject at length and without embarrassment. Our own impressions were gathered at an audience which Dr. Garfield gave to a small group of editors of McGraw-Hill engineering publications.

The fuel order was a military necessity. As such it is not susceptible of explanation in detail without disclosing information to the enemy. It was not designed primarily to save fuel, but to improve conditions in railroad transportation, the demoralization of which was the chief contributing factor to our difficulty. We have

not lacked fuel, but engines and cars with which to handle the freight. The same situation would have developed in some degree if there were no war. It is the urgency of the situation which impresses our lack upon us. The shortage of motive power and rolling stock is attributable, in turn, to the government's policy of the past few years which has resulted in starvation of the railroads. Failure to heed the railroads' requests for an income which would enable them to operate profitably and maintain their equipment in good condition left them unable to serve the country in its crisis.

To all this should be coupled the fact that, with coal in great quantity loaded in cars and standing on the tracks, the Fuel Administration was unable to get a priority order for shipments of fuel to the seaboard, while other favored commodities continued to arrive at coast ports and congest the terminals. This failure to observe a proper sequence in the receipt of coal and other products made it impossible to bunker the ships that were loaded and waiting to transport *materielle*.

The administration of our fuel resources has not been altogether satisfactory, but the trouble has been a lack of co-ordination at Washington—the same trouble, in fact, which is now being revealed, and we hope remedied, in other departments. Recall, for instance, the ill-advised price-fixing which was done hastily to forestall independent action by state governors, the immediate repudiation of the agreement by the Secretary of War, the consequent confusion among consumers and failure to lay in stocks anticipating a lower price, the refusal by Judge Lovett of a priority order on coal and the failure to observe a proper sequence in consignments of fuel and commodities to the seaboard—recall these and the railroad situation, and we can find ample reason for the fuel order. It was inevitable. The weather having been unfavorable to securing the best results from a weakened transportation system, we may expect other closing orders and embargoes on freight.

Too Little Railroad Regulation

NO, THERE is no misprint in the caption. If there is a mistake it is by the editor, not the printer. Most of the talk lately has been of "too much railroad regulation." Perhaps with a qualifying phrase the statement might be correct, that there has been too much regulation of its kind. What occurred was that legislation did not keep pace with the progress of events. The original Interstate Commerce Act, which passed its thirtieth birthday last year, was intended, and very properly, to make railroad charges uniform and eliminate the giving of rebates. That was quite necessary, but other things have since come to be necessary.

The theory of railroad regulation was correct; the application very faulty and altogether incomplete. The theory was that railroads were essential for the development of the country, that the business of the country depended largely upon the railroads, hence the federal government should regulate the railroads. The sugar question is quite a familiar one at this time. It is being regulated, but the public is not satisfied simply with the price being held down. It wants sugar. The price is one thing, the securing of the sugar another. The former is of no use without the latter.

In the case of the railroads only the price has been regulated. No effort has been made to see to it that the public is furnished the service. The railroads have made various pleas to the Interstate Commerce Commission in the past few years that they be allowed to advance rates, pointing out that they were not in position to increase their facilities by reason of insufficient remedies. They did not offer to make a bargain with the commission that if they were granted such and such rate advances they would buy so many locomotives and so many cars, and would build so much track. If they had made such an offer the commission was not authorized by existing law to bargain with them, nor was there any public sentiment that would suggest to Congress the giving of such power to the commission. It matters not whether the increase in revenue would itself have been used or would have been simply the means of improving railroad credit. The matter has usually been looked at as "the railroads borrowing money," but it is broader than that. The issue has been that of capital seeking railroad investment, whether it was in the form of money being loaned to an existing railroad or in some other form.

Railroad men are human, and they have tried to make the best of the situation in which they found themselves. The people decided that rates should be regulated and so they were regulated. The railroads let it go at that.

The people should have decided that the freight-moving facilities of the country should steadily increase year by year with the growth of the country, and should have made provision that this should occur.

The war is merely an incident. War is not the only thing that makes a people busy. We might easily have had the foundation for greater industrial activity than we have if there had been no war. The full activity would not have resulted because men would not work against such odds as they now encounter and strive to overcome because it is war, not business.

Some who comment upon the situation observe that the railroad congestion is greatest at the Atlantic seaboard, and apparently assume that this represents one of the dislocations of war because we are exporting material to our Allies and our own troops. There is much less merchant shipping than there would be at this date if there had been no war, and everyone is counting upon a very large increase in the world's merchant marine after the war, also upon a very heavy foreign commerce for the United States. That would tax the railroads much more than prosecution of the war is taxing them.

What has occurred is simply that the war has opened our eyes to the fact that the existing railroad facilities are insufficient for normal industrial activity. The country has not enough service. Limiting the wages of the servants is not sufficient. Enough servants must be provided. The Director General of Railroads recently testified before a Congressional committee that the railroads might have to be improved, under government auspices, to the extent of a billion and a half dollars being expended. In the light of such a possibility, a prospect indeed rather than a possibility, discussion of how and when the railroads shall be returned to their owners is not to the point. The country needs the traffic facilities both now and after the war. It is a detail who shall own and operate the equipment, and one that can be considered much more intelligently later than at present.

Presentation of Perkin Medal to Auguste J. Rossi

An Account of the Exercises Under Auspices of the New York Section of the Society of Chemical Industry, with Review of Mr. Rossi's Life and Work

IN accordance with an annual custom established in 1906, the New York Section of the Society of Chemical Industry made its award of the Perkin Medal at the Chemists' Club on Friday evening, January 18. The recipient was August J. Rossi, whose contributions to the metallurgy and uses of titanium have distinguished his interesting professional career since 1864.

Dr. Jerome Alexander, chairman of the section, presided. Both the dinner in the Chemists' Club dining room previous to the meeting, and the meeting itself were attended by a large and representative gathering. Rumford Hall was appropriately decorated for the occasion with American and French flags.

Introductory Remarks by Dr. Jerome Alexander

Nothing could be more illustrative of the cordial solidarity that unites us to our Allies, England and France, than this evening's meeting, for here before the New York Section of a British society we are about to award the Perkin Medal to Auguste J. Rossi, a native of France.

France! How the heart of every true American, yes, of every true democrat throughout the world, leaps at the mention of that name! Fair are her fields and beautiful her cities, but France is much greater than all these—her artistic, literary, scientific and spiritual gifts to humanity and civilization have made us her debtors for all time to come, and to-day the civilized world is fighting under her slogan of "Liberty, equality, fraternity."

As a consequence of this dreadful war and under the lash of its stern necessities, we have fortunately been brought in closer relationship with our French fellow chemists. For some months past we have been planning the formation of a New York Section of the French Société de Chimie Industrielle, the sister society of the British Society of Chemical Industry, and to-night, immediately following our meeting, it will be formally organized.

We will therefore proceed with our program, and hear an account of Mr. Rossi's life and work from a gentleman well known to you all, Mr. Francis A. J. Fitz Gerald, past president of the American Electrochemical Society.

Auguste J. Rossi

Dr. A. J. Rossi and His Work

By Francis A. J. Fitz Gerald

IT was, I think, in the year 1899 that I first made Dr. Rossi's acquaintance. There was much speculation in Niagara Falls at that time as to what he was doing. In those days there was always much gossip whenever some new work was started at Niagara Falls, for it was still in the early period of power development, before the MacFarlands and politicians got busy, and we were all watching eagerly the rapid electrochemical developments—aluminium, carborundum, caustic soda and chlorine, calcium carbide, etc. Wonderful stories would float about as to what newcomers were doing. When the Oldbury Chemical Co. started, the most astonishing stories were afloat, caused, I think, largely by the high brick wall which surrounded the factory. It was told with bated breath that this works was engaged in the manufacture of cordite by a new and secret process, and that you could not get inside the brick wall except over the body of an armed guard.

I cannot recall now what various stories were told about some remarkable work in the Porter house and the old stone barn which stood where the Acheson Graphite Company's plant now is, but these were sufficiently startling and all agreed that it was a French chemist named Rossi who was working on some new invention.

I soon made Rossi's acquaintance, for in the electrochemical work of those days there was a fine spirit of co-operation which indeed has become to a great extent permanently characteristic of Niagara Falls, and before long I got to know him very well. During visits to him I learned a great deal about his researches on the smelting of titaniferous ores, about the experiments he was then making on the manufacture and use of ferrotitanium and about many other chemical and engineering works with which he had been associated in his varied professional career. Although I may repeat some things which Dr. Rossi speaks of himself, I believe you will be interested in a brief history of his work.

In the year 1855, at the early age of 16, Rossi graduated from the University of France with the degree of

Bachelier ès Sciences et Lettres, and four years later, after he had also graduated from the École Central of Arts and Manufactures, where the studies covered mechanical, civil and metallurgical work, he came to New York. Here he soon obtained a position as assistant engineer with the Morris & Essex R. R., holding this until 1864, when the railway was taken over by the D., L. & W. After this he got a job which kept him busy for a year, making the survey of a property in Boonton, N. J., which was to be converted into a park under the direction of Mr. Calvert Vaux, the architect of Central Park, New York. Next we find him engaged in building a railway to the Boonton Iron Works, but when Fuller, Lord & Co. of that concern found out that Rossi had studied chemistry and metallurgy at the École Central they put him in charge of a laboratory at the iron works.

It was here that Rossi's attention was first called to titanium, for the ores used in the blast furnaces at the iron works were magnetites from Morris County, N. J., containing in the best samples about 1 per cent titanic oxide and in others 2.5 per cent or more. Beyond noting the existence of titanium in the ores Rossi was not particularly interested in it until he met the work of Professor Cook, the state geologist of New Jersey. This work called attention to the existence of titanium in nearly all the New Jersey ores, from fractions of 1 per cent to as high as 15 per cent titanic oxide. Professor Cook also established a relation between phosphorus and titanium in the ores, low phosphorus apparently going with high titanic oxide content. This set Rossi to work hunting up all the scanty—and, incidentally, very contradictory—literature he could find on the subject of titanium. None of this work was of any practical importance so far as the running of the Boonton Works was concerned, but several years after he had left his metallurgical work to devote his attention to tests on the pumping engines at Fall River, to calculations of the stability of the Beaver Bridge dam, to work on refrigeration and the manufacture of ice-making machinery, his researches on titanium became of value, because of a lawsuit in relation to his old firm of the Boonton Iron Works.

This lawsuit was of great importance so far as Rossi's future work was concerned, as it no doubt established his reputation as an expert in the melting of titaniferous iron ores. Thus, after Rossi had established an office in New York as a consulting engineer, and when in 1890 Mr. James McNaughton was interested in the development of the immense titaniferous ore deposits of the Adirondacks, it was to Rossi that he went for advice. Since that date Rossi has devoted most of his time to titanium.

The problem presented in this case was a study of the feasibility of smelting the titaniferous ores of the Adirondacks. Rossi, as a result of his researches years before, was well acquainted with what had been done in Europe in this field, and of special interest were the records he had of some blast furnaces near Stockton-on-Tyne, England, where ores running as high as 35 per cent titanic oxide had been smelted successfully by forming a slag that consisted of a silico-titanate of lime. This, of course, involved adding considerable quantities of lime and silica to the charge. Here lay the great objection to the Stockton-on-Tyne practice, for on account of the low iron content of the ore it was necessary to make about four tons of slag for one ton of iron.

Rossi told his client that success with the Adirondack ores could be obtained provided that the titanic oxide could be slagged off without using an enormous excess of fluxes, and that so far as the pig iron produced was concerned it would probably be of a very superior quality.

The upshot of the consultation was that Rossi went to examine the ore deposits and two small blast furnaces which had been run there by Mr. MacNaughton's grandfather from 1840 to 1858. In a curious old iron chest Rossi found the blast furnace records. Studying these and knowing the composition of the ore, the fluxes added and the amounts of these going into the charges of the old blast furnaces, Rossi found that the practice of the Stockton-on-Tyne furnaces had been anticipated. He also found that the iron produced was of such superior quality that a gold medal had been awarded it in the great London Exhibition of 1851. Moreover, certain steel made from this iron won high commendation from the navy yards of Springfield and Washington, the report stating that it compared favorably with the best Swedish steel.

Rossi then began a series of experiments on slags with the object of replacing silica with titanic oxide in the normal blast furnace slag, and following his success in this direction, built what might be described as a laboratory blast furnace in which several hundred pounds of excellent pig iron was made from the titaniferous iron ores. Next followed a small blast furnace built at the New York Car Wheel Works in Buffalo, where the Mill Pond ore, running 16 to 17 per cent iron, was successfully smelted.

In this way Rossi did the pioneer work in demonstrating the value of the great ore deposits of the Adirondacks in 1894. Twenty years later we find this work confirmed by Mr. Frank E. Bachman, general manager of the MacIntyre Iron Company, Port Henry, N. Y., in an interesting paper, "The Use of Titaniferous Ore in the Blast Furnace," presented to the American Iron and Steel Institute, October, 1914.

Turning now to ferro-titanium: Rossi was convinced from what he had observed in the work on smelting titaniferous ores that titanium had a beneficial effect on the manufacture of iron. A natural deduction from this was that an alloy of iron and titanium would be of value for the treatment of iron and steel in the process of manufacture.

This led to a series of experiments in small electric furnaces and finally to the construction of larger furnaces in Niagara Falls in 1899, where considerable quantities of ferro-titanium were manufactured, thus permitting of a great number of tests being made on a large scale in steel works and foundries.

This may be considered as closing the experimental period in the development of the manufacture and use of ferro-titanium. Rossi had now convinced himself of its value and the next problem was the education of others in its use.

I shall not go into the consideration of the commercial development of titanium, but merely discuss the principal causes of the great difficulty Rossi experienced in convincing the technical world of the value of his invention.

Perhaps this may be most vividly shown by means of an analogy presented by the practice of medicine.

There are a number of drugs of known value, some of them absolute specifics in the treatment of human ills, but every year we have added to our drug list a number of new medicines. Some of these are at once recognized as of real value by a few, but it often happens that their general recognition is delayed by the exaggerated enthusiasm with which they are greeted at their first appearance; moreover, it frequently happens that the injudicious use of the new drug gives it a bad name. Now, there cannot be any doubt that the very same causes which often delay true appreciation of a new medicine existed in the case of ferro-titanium. Among some there was an unwarranted enthusiasm as to the field of its usefulness and there were plenty of examples of complete failure in its application due simply to ignorance of the proper methods of using it. While, therefore, the value of ferro-titanium has always been recognized by some, there existed for a long time a prejudice against it in the minds of many, and in some quarters this exists even to-day. Thus, in spite of all Rossi showed as regards the possibilities of titanium seventeen years ago, skepticism was for long very general and is not yet completely eliminated. I hope, therefore, that you will pardon me if I call attention to a brief note I made some three years ago on certain statistics in regard to the use of titanium in rail steel, which I think very clearly disposes of the assertions made at that time that titanium has no effect on steel.

In this note are given the statistics of 155 heats, representing the production of 9,000 tons of rail steel, in some of which titanium was used while in others it was not. Where no titanium was used only 36 per cent of the steel came within the particular specification limit. Where 0.053 per cent of titanium was used, 43 per cent passed; with 0.077 per cent titanium, 84 per cent, and with 0.10 per cent titanium, 100 per cent passed.

In the earlier days of the exploitation of titanium the chief drive was made on its use in rail steel, and the data I have given show something of what can be done in that way. But of recent years much greater efforts have been expended in applying titanium to miscellaneous steels. Thus in the last ten years the ratio between titanium going into other kinds than rail steel has enormously increased, for while a decade ago the miscellaneous applications were only 12 per cent of the total they are now 96 per cent and have increased in volume about 150 times.

Thus Dr. Rossi, after more than a quarter of a century of work followed with the greatest perseverance, and undaunted by difficulties of all sorts, has not only shown what can be done with the titaniferous iron ores formerly regarded with distrust by the iron smelter, but has demonstrated that the very element supposed to make these valueless can actually be used for improving the manufacture of the metal they yield.

DINNER AT CHEMISTS' CLUB PRECEDING PRESENTATION OF PERKIN MEDAL

Address of Presentation

By Wm. H. Nichols†

THE world is beginning to get a gleam of what it owes to the chemist, and the chemist himself is beginning to be better understood. As a rule he works so much in the quiet of his laboratory and without the aid of that publicity which is such a prominent part in our life to-day that many of his most important discoveries are made known only to his fellow chemists, who in turn incorporate them in their own fund of knowledge and thus make use of them. Once in a while, however, something very striking comes out of a laboratory and attracts attention by its novelty or by its usefulness, or both. Under this category comes the wonderful dis-

†Past-president Society of Chemical Industry, President American Chemical Society.

covery of young Perkin, which has given the world, through those who have succeeded him, the great synthetic dye industry, the long list of synthetic remedies, and the various contributions to the "gentle art of war," which have followed Perkin's original work. What wonder, therefore, that when fifty years had elapsed, the chemists of the world should fittingly celebrate the work of the young Englishman, and what wonder that the occasion should be seized upon for the founding of a medal to be given to those who, following Perkin, should give to the world something of themselves which should forever be of great value to all mankind! Thus the Perkin Medal was founded, and thus it has annually been bestowed upon some great man who has made the world a better place to live in because he has lived in it himself.

Since the founding of the medal we have been exceedingly fortunate in having it presented annually by our own Professor Chandler, who was the first American selected to fill the great office of president of the Society of Chemical Industry. We have been in the habit of looking forward to these annual occasions, and the part which Professor Chandler would take in them, and I am sure we all greatly regret that he has not found it practicable to be with us to-night to assume this duty which we are so in the habit of associating with him. Unfortunately his health does not permit it, but let us hope that next year, and for many more to follow, he will stand in this place and perform this act in his usual graceful manner. It, therefore, falls to my lot as the next succeeding president to present the medal, and this task I undertake with great diffidence, feeling, as I do, the great disappointment which you all sustain in not hearing from the grand old man himself. It is not, however, the first time in which I have undertaken this work, as I had the honor of presenting the first Perkin Medal to Perkin himself during the jubilee celebration in New York.

It is particularly appropriate that this medal should be presented at one of the stated meetings of the New York section of that great English Society of Chemical Industry, which counted among its presidents so many great Englishmen, including Sir William himself. During the recent terrible years the members of this society have almost remade Great Britain from a chemical standpoint. Similar work of the highest grade has been accomplished by our French brethren. American chemists have taken great interest in the British society, and they are now to have an opportunity of doing similar work for the Société de Chimie Industrielle, the New York section of which is to be formed to-night. We have always had a warm place in our hearts for our French friends, and I am glad that we are going to have an opportunity of again proving this, if any proof be necessary.

You have heard from Mr. Fitz Gerald a statement of some of the work which Dr. Rossi has done, and it is not my intention to add to that list a single statement. If Mr. Fitz Gerald has omitted anything, Dr. Rossi himself will please supply as much of the deficiency as his modesty will permit.

Dr. Rossi, there have been several candidates for the honor which is to be conferred upon you to-night. The claims of each have been carefully weighed by a committee, whose only desire has been to select the candidate best qualified to receive the medal this year when everything has been considered. You have been their choice and are, after a long life full of hard work and the usual disappointments that come to every successful man, to receive the greatest reward which your fellow chemists can bestow upon you. You are joining a body of very brilliant men. You may well feel gratified that those who know best consider you worthy of the honor of that company, and in token of that selection I beg to express to you what I am sure is the thought of every man in this room, and of every other who knows your word, our hearty congratulations on a life well spent, and our cordial *bon voyage* as you turn your face to the setting sun. Coupled with this is the hope that you have before you yet many days of usefulness, and that you will be able to return our confidence with something of even greater value than what has gone before. With a heartfelt respect of the entire chemical fraternity, and a handclasp as its token, it is my privilege to present to you the Perkin Medal of 1917.

In accepting the medal Mr. Rossi expressed his heartfelt gratitude to his fellow chemists for the honor they had conferred upon him, and his appreciation of the fact that, after all, the award was not so much for personal merit as it was a recognition of those qualities of perseverance, thoroughness and devotion to science which mark all genuine research. He then gave an interesting account of his experience in the metallurgy of titanium. An excerpt of his address follows:

Development of the Metallurgy of Titanium

By Auguste J. Rossi

My special attention was directed to the possibilities of titaniferous iron ores in 1890 by Mr. James MacNaughton, a graduate of Yale interested in the immense Adirondack deposits as an inheritance from his grandfather, Mr. MacIntyre. These deposits were of such a magnitude that Mr. Birkinbine, then president of the American Institute of Mining Engineers, said of them at the Montreal meeting of the Institute in 1893: "Providence seems to have placed these titaniferous deposits right where they are the most inviting * * * on the headwaters of the Hudson river." I had been directed to Mr. MacNaughton by Professors Chandler and Ricketts as one who could give information on this subject, for I had had occasion previously to write a paper entitled "Titanium in the Blast Furnace" for the American Chemical Society.

Having been for some eleven years (1864-1876) technical director of the Boonton blast furnaces (Boonton Iron Works—Fuller, Lord & Co., proprietors), I knew from actual practice that the presence of titanium oxide (TiO_2) to an average of 1.5 per cent in the Morris County, New Jersey, ores, which we were smelting, and of some 2 to 2.5 per cent in our slags, had had absolutely no effect on the working of our furnaces or the behavior of our slags as to fluxidity and fusibility, so much so that I even ignored its presence and considered it as so much additional silica in the ores.

And still when the question arose of smelting these ores, alone or in mixture, one could read in the proceedings of a well-known scientific technical society "that 1 per cent of TiO_2 in a slag was enough to make it pasty to impossibility of tapping!" The advance copy of the paper (in my hands) says "that the slags had to be pulled out with tongs." How could young men new in the profession be blamed for being skeptical about the

smelting of this class of ore after such statements as I have quoted *verbatim?*

In 1876 the death of the two owners forced the closing of the Boonton Iron Works. The furnaces were blown out but not dismantled. Workmen and all had to leave and the small town was deserted for several years.

Later on in the 80's Mr. Eckert of Reading, Pa., who was making there what is called stove iron, having decided to use our puddled cinders, of which we had years of accumulation, with some of our ores containing 2 per cent TiO_2, leased the two blast furnaces which were still standing, with all the blowing apparatus and appurtenances. They made a failure of this run for technical reasons foreign to my subject and which could easily have been foreseen by one familiar with blast furnace work. However, having stopped the furnaces after a very few months' run, they tried to get out from their contract binding them to use a stipulated number of puddled cinders and ores by claiming that the presence of TiO_2 in our cinders and ores had been the cause of their failure. I was retained as an expert by the estate and had no difficulty to prove by my books of analyses and statements of founder and others that the presence of TiO_2 to the extent of their own analyses was in no way greater than the amounts which I had found during an eleven years' practice to have had absolutely no effect on the working of the same furnaces. They had to compromise and pay a heavy forfeit. I have entered into these details to render intelligible what follows.

The suit came before the Chancellor of New Jersey and I have on hand the brief submitted by the plaintiff, containing all sworn testimonies of their experts.

One of the experts, manager of one of the Durham furnaces (Cooper, Hewitt & Co.), testiled under oath that 0.75 per cent of TiO_2 in an iron ore rendered it unfit for blast-furnace purposes, as it would be only a matter of a short time before the furnace would be "clogged up" if the use of the ore were not stopped. Another(also a manager of a Durham furnace, testified under oath that not 0.75 per cent but 0.25 per cent of TiO_2 in an iron ore precluded its use in a blast furnace, it being merely a matter of a little longer time before the furnace would be clogged up. Mr. Eckert testified that "from his twenty years' practice in iron-making in blast furnaces not 0.25 per cent but *traces (sic)* of TiO_2 were sufficient to produce the same result as above mentioned.

Repeated Success in Smelting Titaniferous Iron Ores

This is only one of the many examples of the criticisms, prejudices and objections I met in my fight for these much abused ores. Such was the encouragement I found in the profession! Then in 1894, at the New York Car Wheel Works, Buffalo, N. Y., in a small furnace of three to four tons daily capacity, I melted, without mixture, titaniferous iron ores from the Adirondacks, containing 15 to 18 per cent TiO_2 and 55 to 56 per cent metallic iron. The slags as run from the furnace analyzed 25 to 30 per cent TiO_2, with some 15 to 18 per cent silica and lime, alumina and magnesia as bases, magnesia having been recognized by me as an essential constituent to insure the best running. These ores, being inaccessible to a railroad, had to be transported on corduroy roads to North Creek, where they could be loaded on cars. This brought their cost to $15 per ton delivered at Buffalo. This precluded the idea of making a test on a larger scale unless we could find a furnace of some ten tons capacity, which it proved impossible for us to do. Later on, within the last two years, Mr. Bachman melted similar titaniferous iron ores in one of the large blast furnaces of Weatherbee, Sherman & Co., at Porth Henry, making some 15,000 tons of a pig iron which he found of superior quality. In a very elaborate, comprehensive, scientific and technical report Mr. Bachman has given the fusibility and fluidity of the titaniferous slags run in the furnace, analyses of all materials and results of tests for strength as compared with that of the average pig irons made without titaniferous iron ores in the charges. His conclusions as a whole are a confirmation of my own as drawn from this run in Buffalo in 1894-95 in my small furnace. One of them particularly is worth mentioning, as I had come to the same conclusion in Buffalo. He says: "This run with titaniferous ores was made with an economy of fuel per ton of pig metal smelted," and yet one could read in technical publications in 1894 "that the smelting of titaniferous ores even if admissible meant such an excessive consumption of fuel per ton of iron that on this score alone they are unsuitable," leaving aside "titanium deposits in the furnace and pasty slags." This is an obvious contradiction, for if the furnace is "clogged up" by titanium which remains in the furnace, it does not go in the slag and the latter need not be pasty; or, if it goes in the slags, making them pasty, it does not remain in the furnace as titanium deposit. These titaniferous ores of the Adirondacks are magnetic, associated with ilmenite ($FeTiO_3$), an iron titanate, just as iron silicate ($FeSiO_3$) is found in certain ores (ferruginous peridotite). They are, like almost all titaniferous ores, low in phosphorus and sulphur, some as low as 0.017 per cent P and 0.02 per cent S, with 55 to 56 per cent metallic iron and 1.50 to 2 per cent SiO_2. The iron smelted from them makes an ideal open-hearth steel, and in our day open-hearth steel has superseded Bessemer steel.

Tests made by me, and in many foundries, of such pig metal added to ordinary pig iron in certain proportions has shown an increase of strength "over cast iron not treated of 29½ per cent in tests made and reported by Wm. Cramp & Co. and an increase of 4 per cent over cast iron treated with nickel."

If the results of such work as I have done, confirmed by the very recent blast-furnace runs on a large scale made by Mr. Bachman, will call the attention of metallurgists to these much abused ores, I will not have worked in vain.

Pioneer Work with Titanium as a Ferro-Alloy

But whatever value these ores may have, alone or in mixture with other ores as blast-furnace stock, their use for making alloys of iron or copper with titanium for the treatment of cast iron, steel, copper or copper alloys has opened a new and more important field of application in metallurgy.

Checked by the difficulties encountered in my efforts to secure such quantities of ore as are required for blast furnaces of our present size and capacity, I proposed to Mr. MacNaughton in 1900 to make a concentrate of titanium which, added to ordinary cast iron

or steel, would be likely to secure for the metal baths thus treated the same beneficial effect which tests had shown in pig metal smelted from these ores.

I may say here that Mr. MacNaughton was the one who supported me in these times of trial by his implicit confidence in me and the possibilities of my work.

About 1900 I started making ferro-titanium at the old Porter house in Niagara Falls by reducing titaniferous iron ores in an electric arc furnace. I used preferably those ores containing the highest percentages of TiO_2, such as ilmenite containing 40 per cent TiO_2 and 50 per cent more or less oxide of iron, or even rutile containing 93 to 95 per cent TiO_2. The furnace, being made of a masonry of graphitic material, formed the cathode and a carbon electrode, which was movable vertically by means of a mechanical device, or automatically by the current itself, formed the anode. A properly comminuted mixture of the titaniferous material and of the carbon required for reduction of both TiO_2 and oxide of iron was charged gradually into the furnace as the current was turned on. Whenever the relative proportion of TiO_2 and oxide of iron were such as to produce an alloy higher in titanium than was desired, some scrap iron was charged with the mixture to dilute the alloy, so to speak. In this manner I made alloys containing from 10 per cent to 25 per cent or more, but practice in steel and other works has shown that an alloy containing some 15 per cent of titanium was best suited for most purposes.

Whenever the presence of carbon in the ferro-carbon-titanium was considered objectionable for special applications, I reduced the titaniferous materials by my aluminium-bath process. Instead of using a mixture of finely powdered aluminium and titaniferous material, as in Goldschmidt's thermit process, the aluminium I used for the reduction of the oxides was melted in the electric furnace and the titaniferous materials charged directly into the bath. In such cases I used preferably TiO_2 as rutile in order to avoid using the aluminium which would have been required for the reduction of the oxide of iron of the ore, charging scrap iron with the rutile to dilute the alloy to the desired content of titanium. In this manner I made ferro-titanium practically free from carbon, containing only from 0.18 to 0.50 carbon, and by reducing the amount of scrap iron added I was able to make ferro-titanium as high as 80 to 85 per cent titanium.

Titanium as a metal is as white and as shining as silver, but very hard and brittle, so that it has no particular use as such. Alloys high in titanium, such as 75 to 85 per cent, and even those with less tenure in titanium, are also white like silver and scratch glass and even quartz deeply.

This aluminium bath process is of more general application. Thus if a tungstic ore containing oxide of iron is charged, a ferro-tungsten is obtained free from carbon. I have made thus 85 per cent tungsten alloy. By using manganiferous ores I was able to make in the electric furnace 85 to 88 per cent ferro-manganese free from carbon, and by using chromic iron, a ferro-chrome of about 80 per cent chromium free from carbon.

Effect of Titanium in Steel

By adding to a bath of steel or to cast iron a ferro-carbon-titanium containing some 15 per cent of titanium, the bath of metal was cleansed from dissolved or occluded gases, such as oxygen and nitrogen, and from oxides of iron generally present in steel, specially in Bessemer steel. When air is blown through the molten pig iron the titanium of the alloy combines with oxygen as TiO_2; with nitrogen as titanium nitride. The oxide of iron is reduced to iron by the titanium and the carbon of the alloy, the titanium combining with its oxygen to form TiO_2. The slag, always present in metallic bath, rises and carries with it the titanic dioxide and the titanium nitride to the top of the ingot or ladle. The TiO_2 entering the slag renders it more fluid and fusible, as proved by experiments I have carried on for Dr. P. H. Dudley, the expert of the N. Y. C. R. R. A slag collected by him at the top of an ingot and containing 6½ per cent of TiO_2 had a melting point of 1290 deg. C., lower than or about the same as that of an ordinary blast-furnace slag. By adding enough TiO_2 to such a slag to have in it some 13 per cent TiO_2, its melting point was lowered to 1190 deg. C., as determined by Mr. Fitz Gerald.

The presence of titanium in steel to the extent of 1 per cent or more imparts to the steel certain very special properties to which, later on, I may have occasion to direct your attention. The head of a crucible-steel ingot treated with titanium cast in 1900 at Atha & Illingworth, East Newark, had five holes drilled in it to obtain specimens for analysis. These holes are as bright now as they were when first drilled, though exposed to the air in my office. This ingot contains 1.10 to 1 per cent titanium, and the steel was so hard that it was drilled with difficulty.

Copper, as is well known, absorbs when melted, a large amount of gases, and the bath contains oxide of copper. For the treatment of copper and its alloys, such as bronze, brass, manganese or aluminium bronze, I have made a copper-titanium containing any amount of titanium, though 10 to 15 per cent appears better adapted as a scavenger of the copper bath. I have also made aluminium-titanium containing 45 per cent titanium for seasoning aluminium bronzes. They are made in the same manner as ferro-carbon-titanium or ferro-titanium in the electric furnace. For copper-titanium, TiO_2 and aluminium are charged in the furnace in a bath of copper. For aluminium titanium, the TiO_2 is charged directly in the bath of aluminium. The reaction of aluminium on oxides being exothermic, much less current is required for the reduction proper.

As is well known, the affinity of titanium for O and N is such that the metal burns at 800 deg. C. or thereabout in an atmosphere of these gases. (Wöhler and St. Claire Deville). It is so strong that when large cakes of alloy free from carbon are broken while hot the section exposed to the air colors itself with fine iridescence, presenting all the colors of the rainbow: blue (probable TiO), gold (probably nitride), copper (probably cyanonitride formed by the small amount of carbon still present), and combinations of these.

I have experimented with ores containing 1.50 to 2 per cent of phosphorus, adding even apatite (lime phosphate) to the mixture, so as to obtain a pig iron as high in phosphorus as I could. Contrary to what might have been expected, the pig metal containing 0.40 titanium and from 2.50 to 3.50 per cent phosphorus had the strength of fair No. 1 or No. 2 pig iron. This suggested treating phosphoric pig metal, generally weak and close grained, with ferro-titanium, so as to incor-

porate a divided amount of titanium in it. The results were very encouraging and were presented by me at the Pittsburgh meeting of the A. I. M. E. in 1896.

I have also experimented with the smelting of titaniferous ores in mixture with manganiferous ores, even in a coke furnace. I was able to introduce some 3 per cent to 3.50 per cent of titanium in cast iron, and by addition of MnO_2 the pig iron contained 2 to 3 per cent Mn. Manganese appears to cause the titanium to pass into the cast iron, as it alloys readily with titanium.

Other Titanium Compounds

If a ferro-titanium practically free from carbon, made by my aluminium bath method, preferably as high in titanium and low in iron as possible, is dissolved in hydrochloric acid, a fine violet solution is obtained—a ferrous titanium chloride. With this violet solution I have been able to bleach cotton, silk and wool. As is well known, silk and wool cannot be bleached in agents capable of generating free chlorine, which injures and attacks these fabrics. Still I was able to bleach completely some 2000 yards of such fabrics by digesting them in this diluted violet solution, boiling for a shorter or longer time, according to the intensity of the dye to be bleached or the yellowish tint of the white fabrics. Silk and wool, colored or yellowish, were thus bleached without injury to the fabrics. The double chloride contained about 40 to 50 per cent $TiCl_3$, titanous chloride, the balance ferrous chloride. During the operation, especially as the temperature reached near the boiling point, TiO_2 precipitated, thus showing clearly that the chlorine must have been set free and must have combined with the ferrous chloride to form ferric chloride, the chlorine generated acting in the nascent state without even coming as free chlorine in solution.

The fact that TiO_2 was precipitated from one of its compounds by organic matter suggested to me the possibilities of precipitating TiO_2 from others of its compounds by vegetal or animal organic matter. The results were very remarkable. If to a solution of titanic sulphate $Ti(SO_4)_2$ is added a water extract of organic vegetal or animal substance, and the liquid gently digested to boiling and boiled for a short time, TiO_2 is precipitated and, when calcined, is obtained as a soft, smooth, flourlike, pure white powder, requiring no mechanical pulverization. This is such a characteristic of the action of these organic substances that a number of them, such as water extracts obtained from dry leaves, green leaves, sawdust, tannin, wood pulp, woodpulp liquor, horse chestnuts, beans, docks, cranberries, radishes, etc., and urea itself, have given the same results. One of the interesting features of this process of obtaining TiO_2 pure white and smooth in impalpable powder is that if this same titanic sulphate solution be precipitated by NH_4OH or Na_2O, and boiled, the TiO_2 calcined is granular.

This method finds a direct application in the production of a white titanic pigment, a product which our company is to manufacture on a large scale. Calcined TiO_2 possesses a remarkable property of covering when used as paint material, alone or in mixture with such other pigments as are used in the trade for paints. Its superiority on this score, when prepared with proper oils, over white lead or white zinc is remarkable, and, besides, TiO_2 pigment is not attacked by gases.

Chemical Alliance to Meet

THE first annual meeting of the Chemical Alliance, Inc., will be held at the Hotel Biltmore, New York, on Wednesday, Feb. 6, at 9 a. m. As previously stated in our columns, the Chemical Alliance, Inc., has taken over the work of the Committee on Chemicals of the Council of National Defense, and has a permanent office at 540 Woodward Building, Washington, D. C. Membership in the alliance is open to all individuals, firms or corporations in the United States engaged in the chemical or allied industries. The annual dues are $25 with no entrance fee charged. Sections already organized include Acids; Coal Tar By-Products; Electrochemical; Fertilizers; Alkali, and others. The meeting on Feb. 6 will be open to qualified manufacturers whether or not they are yet members. A large attendance is anticipated.

American Dyestuff Industry Organizes

ALMOST important forward step was taken by American dyestuff manufacturers and allied interests when they formed a permanent organization at the Chemists' Club in New York on Jan. 22 and 23. Practically all of the important manufacturers and dealers were present and the interest shown and results accomplished speak well for the future of the industry in this country.

The meeting was called to order at 10.30 a. m. on Jan. 22 by H. Gardner McKerrow, the father of the movement to form a permanent organization. Frank Hemingway was chosen temporary chairman and made a short speech outlining his idea of what the aims of the organization should be. He laid especial emphasis on the value of meeting together socially and discussing each other's problems. He urged a quality membership and the formation of a committee of organization. C. D. Jenkinson of the National City Bank was chosen temporary treasurer and C. C. Bennett of the Color Trade Journal, temporary secretary.

The chairman then called on Mr. McKerrow to outline the objects of the convention. Mr. McKerrow mentioned some of the pressing problems confronting the dye industry, such as standardization, tariff, patent laws, arbitration of disputes, prevention of inferior exports, protection of contracts, etc. Others who spoke during the two days were Dr. J. Merritt Matthews, Dr. Wallace Pierce of the United States Conditioning and Testing Laboratories, who spoke on "Standardization," Mr. Bradford Webster, who spoke on "Arbitration," Mr. A. E. Parker, who spoke on "Patent Law," and Dr. Grinnell Jones, who told of the work the Tariff Commission is doing in regard to the dyestuffs tariff. Dr. Jones has been asked to make recommendations to the commission in about four weeks. A committee was appointed to confer with Dr. Jones.

On the first day of the meeting an organization committee was formed consisting of Messrs. L. A. Ault, J. Merritt Matthews, Mr. David, H. G. McKerrow, August Merz, Mr. Woodward and Mr. Hyndman. This committee will formulate recommendations for a name for the organization, by-laws, classes of membership, etc., and report at the Annual meeting to be held March 6 at the Chemists' Club.

The Physical Properties of Copper and the Factors by Which They Are Affected—I*

BY PAUL D. MERICA
Division of Metallurgy, U. S. Bureau of Standards

At no time in the history of the technology of metals, their production and manufacture, has the necessity for accurate information concerning their general physical properties been more keenly recognized in the industries than to-day. The day is not far past when the scientist, either chemist or physicist, in the manufacturing plant was considered a luxury, and qualitative or even comparative knowledge of the characteristics of materials was considered quite sufficient for every-day plant operation. With industry's tremendous growth and ramification, however, has come increased demands for performance upon the materials at its disposal, which has been possible of fulfillment only through more detailed and accurate study of the characteristics of these materials than was considered necessary before. Not only has it become necessary to study more thoroughly and quantitatively than before characteristics which already were utilized, but it has become necessary to pay attention to characteristics of materials which formerly were hardly considered of more than merely scientific interest. Thus have the thermo-electric properties of metals been of late the subject of quite intensive investigation.

This growing realization of the manufacturing industries, that increasingly they require accurate physical data on metals and alloys, has been borne in upon the writer by the numerous requests for such information which come to the Bureau of Standards, and so frequently has he had occasion to search the literature for accurate and dependable data concerning this or that characteristic of a metal or alloy in answer to their requests and for his own purposes, that he has often wished that such might have been grouped in one place, that it might be more generally and readily accessible to those for whom it is of interest.

In view of these demands therefore it seemed of sufficient importance that an attempt has been made, as a beginning, to assemble for the metal copper all of the most reputable physical data in the form of a sort of handbook of information, as well as to give the complete bibliography of the data for those who might wish to examine them critically. In this compilation the data and information have been put in the form of tables and curves, the latter being reproduced in such dimensions that accurate interpolation of values on them is possible by the use of a rule graduated in decimal parts of an inch. The probable degree of accuracy of data is indicated by the number of significant figures in the values given. The bibliography is given at the end and contains the sources to which the numbers refer.

The actual labor of assembling these data has been most amply repaid, the author feels, by the instructive facts which have thereby been brought to his attention.

In the first place it is most interesting to note the characteristics which have received the most attention and which have been quantitatively most accurately studied—characteristics, almost always, of technical and industrial significance, as for example, electrical conductivity, in the case of copper. Industry has been served by science as never before.

Another interesting fact is apparent in the study of such data, namely, the lack of recognition on the part of the scientist who has measured physical properties of the magnitude of the effect of the physical state and the chemical purity or composition upon these properties. The author has seen instances in which a property has been measured most carefully and by most elaborate apparatus, using a sample of material not physically or chemically sufficiently defined that an error of ten times the experimental error would have been of significance. It has remained for the experience of the manufacturer and producer of metals to guide the physicist in his physical studies of such material.

This article therefore attempts to consider the physical data of copper in relation to the chemical purity of the copper and to its physical state, by which these properties are often most markedly affected. There are several chapters which could be most satisfactorily elaborated if the experience of several manufacturers in copper were available, such as that for example on the defects or "disease" of copper, and that upon the effect of impurities on the properties of copper. It is to be regretted that information of this sort which is based upon day-by-day close observation of this metal and which is of such great technical significance should not be at least in large part the property of the technical world; if this article by its very incompleteness in those chapters induces a change in the attitude of those having such private store of information, it will have most amply served its purpose.

METALLOGRAPHY OF COPPER

The purest copper produced commercially, that which has been electro-deposited and not remelted, or has been remelted *in vacuo*, consists structurally of an aggregate of copper grains or crystals, the latter belonging to the regular or cubic system. Photomicrographs, Figs. 1 and 2, show pure electrolytic copper as deposited in the form of cathode strip, not remelted. Figs. 3 and 4 show copper as deposited in the form of electrotypes (38), and show the twinning in the columnar crystals and the etching pits inside of the grains.

When copper is remelted, it takes up oxygen, only part of which is removed by poling, such that about 0.05 per cent remains in the ingots cast from the fur-

nace. The appearance of such cast copper is shown in Fig. 5. The oyxgen is present as Cu_2O, which forms a eutectic with copper of the composition 3.45 per cent Cu_2O, melting at 1063 deg. C.; it is not appreciably soluble in solid copper. It presents under the microscope a bluish-gray appearance with a characteristic

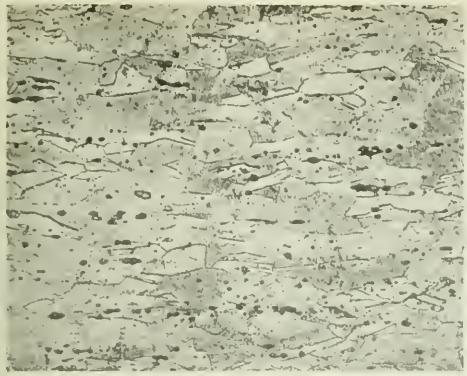

FIG. 7. MEDIUM-DRAWN WIRE, 7 64 IN. × 250

FIG. 8. SOFT WIRE, $\frac{1}{4}$ IN. × 250

red "glow" at the center of each particle, and cannot be confused with other inclusions in copper. The Cu_2O content of cast copper may be readily determined planimetrically from photomicrographs or on microscope ground glass (33).

The structure of such cast copper is broken up by the mechanical and heat treatment it receives in the mill, and it recrystallizes, appearing as shown in Figs. 6, 7, 8 and 9, illustrating different forms of commercial copper. The oxide is present in rows of fine globules, parallel to the axis of forging or working.

In the hard-drawn copper (Fig. 6) the grains are crossed by numerous etch-bands, perpendicular to the direction of drawing, and characteristic of hard copper; the grains are also elongated in the same direction. This is true also, but in less degree, of the medium-drawn wire, Fig. 7. When hard-drawn copper is annealed it recrystallizes; fine grains make their appearance within the larger original strained grains and generally at the border of the grains or along twinning planes and grow. The recrystallization takes place simultaneously with the softening of the metal; the temperature ranges of recrystallization coincide with those of the annealing softening (see Fig. 19), *i. e.*, from 250 deg. to 400 deg. C. After a full anneal the metal assumes the structural appearance shown in Fig. 8.

Figs. 9 and 10 show the appearance of hot-rolled copper plate or sheet, $\frac{1}{4}$ in. thick.

The grain size of copper may vary within wide limits. When just recrystallized, after cold-drawing or rolling, the grains will have diameters of from 0.0005 to 0.003 in. approximately, whereas after annealing at higher temperatures the diameters may go up to from .005 to .015 in. The grain size depends upon the extent of the reduction and of the annealing; this in commercial practice depends on the size of specimen, so that one may find in hard-drawn heavy sections a grain size larger than in soft smaller sections. The presence of oxide particles has been shown to hinder grain growth, in preventing coalescence of the adjoining grains.

Besides Cu_2O, bismuth and lead, when present in copper, are present at least except in quite small amounts (see below) as discreet particles, visible under the microscope. Other impurities, silver, gold, nickel, manganese, arsenic, antimony, zinc, phosphorus, etc., dissolve to a greater or less extent in the solid copper and leave no microscopic trace of their presence, except pos-

sibly in the cast state, when their presence gives a cored or dendritic structure to the metal.

Copper is best etched for microscopic examination with ammonium hydroxide, with ammonium persulphate solution or with a combination of the two; hydrogen peroxide may be used with ammonium hydroxide in place of ammonium persulphate.

Bragg (35) has shown by his method of X-ray examination that the copper atoms in crystalline copper are arranged in a face-centered cubic lattice; there is therefore apparently no copper molecule in solid copper smaller in size than the grain itself.

1. Possible Allotropy; Transformation

It is generally assumed that copper does not exist in any allotropic forms, but that the form which is stable at ordinary temperature persists also at lower and higher temperatures. Thermal analysis and microscopic examination disclose no evidence of any chemical transformation of any sort.

Cohen and his co-workers (42, 43) from measurements and consideration of the thermal expansion and electrical resistance, believed that they had discovered in electrolytic copper a transformation point at about 70 deg. C. The very careful electrical resistivity measurements of Burgess and Kellberg (41) do not however indicate any such point; the electrical resistivity varies almost linearly in a smooth curve between 61 deg. and 74 deg. C. The results of Cohen are possibly to be attributed to the presence of Cu_2O in the copper tested or to the fact that the chips or wire used were in a state of initial stress or of unstable (fine) crystal structure.

Schützenberger's (45) allotropic copper has been shown by Benedicks to owe its properties to inclusions of Cu_2O and acetate of copper. It is harder and more brittle than copper and is made by the electrolysis of slightly alkaline solutions of copper acetate.

CHEMICAL PROPERTIES

Copper is not oxidized in dry air at ordinary temperature nor in moist air in the absence of CO_2. In dry air the oxidation at temperatures under 180 deg. C. is insignificant; above that temperature are formed CuO and Cu_2O. It is not readily attacked at temperatures below the melting point by H_2, N_2, CO, CO_2 or H_2O. Elliott claims that superheated steam makes copper brittle. In the presence of NH_4OH copper is readily oxidized in air; this reaction is utilized as a method of ozone O_3 absorption.

Copper does not dissolve in the absence of air in dilute HCl or dilute H_2SO_4, but readily in HNO_3, and also in KCN. In the presence of air, dilute acids, including certain organic acids, attack it slowly; at higher temperatures concentrated H_2SO_4 attacks it, forming SO_2, $CuSO_4$, etc. It is also corroded slowly by saline solutions and sea water.

Foerster (3) discusses the anodic and cathodic electrochemical behavior of copper, characteristics of great importance to the electrolytic refining industry.

Heath (8) describes the methods in use for the analysis of copper and its alloys.

PHYSICAL PROPERTIES

1. Electrical, Magnetic

(*a*) *Electrical Conductivity.* — The International Electrotechnical Commission in 1913 adopted the present international standard value for the electrical resistivity of annealed copper; this is

0.15328 ohm (meter, gram) at 20 deg. C.
0.017241 ohm (meter, mm²) at 20 deg. C.
0.67879 microhm (cu. in.) at 20 deg. C.

This value is based upon the values obtained by the various national physical laboratories (49, 60) for ordinary high-grade commercial refined copper in the annealed state; it represents an average value for such materials. The standard density is 8.89 grams per cubic centimeter.

Investigation made at this bureau showed that for 89 annealed samples of the purest commercial copper from fourteen refiners the mean value of the resistivity was 0.15292 ohms (meter, gram), the average deviation from this value being 0.26 per cent, the maximum, 1.7 per cent. It is thus seen that even in the purest grades of copper the variation in purity and physical state are sufficient to cause variations in resistivity of annealed samples of about ± 1.5 per cent. Some of the highest values found for the per cent conductivity of copper are the following:

Resistivity = 0.15045 ohms (meter, gram) at 20 deg. C. (annealed wire).
Per cent conductivity = 101.88 per cent.
Resistivity = 0.15386 ohms (meter, gram) at 20 deg. C. (hard-drawn wire).
Per cent conductivity = 99.62 per cent.

The first value (60) is for an annealed wire drawn

directly from a mass of native lake copper which had never been melted. The second value is for a hard-drawn sample drawn directly from a cathode plate without remelting. The average difference between the conductivity of hard-drawn and of annealed copper is 2.7 per cent.

It may be noted that in the investigation by this bureau of about ninety samples of commercial pure copper, the electrolytic samples, annealed, gave a mean value of 100.3 per cent, the lake samples, one of 100.02 per cent conductivity. The electrolytic samples also averaged about 0.40 per cent higher than the lake samples in the hard-drawn condition. According to Mr. Bassett, Technical Superintendent and Metallurgist, American Brass Co., "it is not uncommon to find a conductivity in commercial wire bars of 101.3 per cent to 101.6 per cent when soft-annealed."

It may be noted that the electrical conductivity, as also its temperature coefficient, afford very sensitive criteria of the purity of copper, and are most convenient

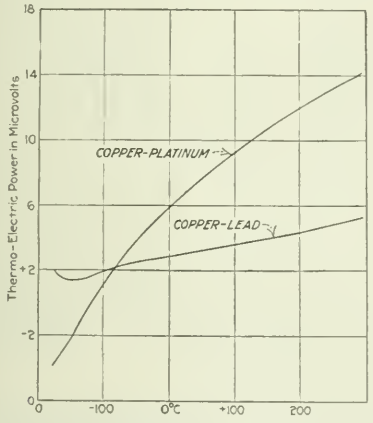

FIG. 11. THERMO-ELECTRIC POWER OF COPPER TO PLATINUM AND TO LEAD. (ADAMS)

when the metal is to be tested in the form of wire or rod.

Within the temperature limits 10 deg. to 100 deg. C. the conductivity of copper is a linear function of the temperature (within 0.2 per cent) (50), and the temperature coefficient of resistance is proportional to the conductivity; e. g.

$$\alpha\ 20^\circ = 0.0000393 \times \text{per cent conductivity.}$$

Thus as a consequence of this relation the change in resistivity per degree centigrade is a constant for copper, independent of the temperature (10 deg.-100 deg. C.) and of the purity, and is equal to 0.000597 ohm (meter, gram, deg. C.).

(*b*) *Thermo-Electromotive Force, Peltier Effect, Thomson Effect.*—In. Fig. 11 are given the curves of the thermo-electric power (dE/dt) of commercially pure copper to pure lead and platinum as determined by Dr. Adams (61), of the Geophysical Laboratory of the Carnegie Institution. According to him the thermal emf. of different samples of commercial copper wire to lead or platinum does not vary by more than 5 microvolts at 200 deg. C., showing a remarkable homogeneity of this metal in its commercial form. From these curves cubic equations have been derived as follows:

$$\text{(Cu-Pt)}\ \frac{\delta E}{\delta t} = 5.85 + 0.0406t - 7.46 \times 10^{-5}t^2 + 1.096 \times 10^{-7}t^3$$

$$\text{(Cu-Pb)}\ \frac{\delta E}{\delta t} = 2.84 - 0.0082 - 0.84 \times 10^{-5}t^2 + 0.226 \times 10^{-7}t^3$$

The thermal emf.'s are obtained by integration as follows:

$$E'_0 = \int_0^t \frac{\delta E}{\delta t}\ dt$$

$$\text{(Cu-Pt)}\ E'_0 = 5.85 + 0.0203t^2 - 2.48 \times 10^{-5}t^3 + 0.274 \times 10^{-7}t^4$$

$$\text{(Cu-Pb)}\ E'_0 = 2.84 + 0.0041t^2 - 0.28 \times 10^{-5}t^3 + 0.0565 \times 10^{-7}t^4$$

The emf. of copper to lead was calculated from the direct data of Adams on the emf. of copper-lead and of lead-platinum.

Adams and Johnston (62) give a general equation for the copper constantan couple, to be used in connection with deviation curves given by Sosman (66). The equation is:

$$E = 38.105t + 0.04442t^2 - 0.00002856t^3$$

The Peltier and Thomson effects may be calculated from the above equations.

(*c*) *Electrolytic Solution Potential.*—The electrolytic solution potential of copper to a solution containing its (bivalent) ions is given by Neuman (74), who found for

Cu NCuSo$_4$(18 deg. C.) normal hydrogen electrode: $E_h =$

-0.308(Cu ion concentration $= 0.11\ N$)

E_h calculated $=$

-0.329(Cu ions in CuSO$_4$ solution of N concentration)

Labendzinski (73) has determined with care the emf. of copper to its cupric salts. His results are as follows:

	Normality	E_h
Cu/CuSO$_4$	1.0	+ 0.304
	0.1	.284
	0.01	.262
Cu Cu $(NO_3)_2$	1.0	.331
	0.1	.294
	0.01	.266
Cu Cu (acetate)	Saturated	.278
	0.1	.264
	0.01	.242

Cohen (69) has shown that the emf. of copper amalgams of mercury content of from 1 to 16 per cent to a saturated solution of CuSO$_4$ at 25 deg. C. to Hg$_2$SO$_4$, Hg is 0.3471 volts.

The emf. of copper to solutions containing cuprous ions has been studied by Bodländer-Storbeck (71). They find that for Cu 0.05 NKCl + saturated CuCl:

$$E_h = -0.194 \text{ volts}$$

The emf. of copper to solutions of its salts (cupric) become less negative with increase of temperature (72). The temperature coefficient of emf. between 0 deg.-50 deg. C. is

$$\alpha = 0.00066 \text{ volts per degree C.}$$

(*d*) *Magnetic Properties.*—Pure copper is diamagnetic. Its magnetic behavior is very profoundly altered by slight traces of iron present as an impurity. Thus as little at 0.04 per cent of iron makes copper paramagnetic (75, 77). Values given for K, the susceptibility, are

$K_l = -0.66 \times 10^{-6}$ (79)

$= -0.82 \times 10^{-6}$ (electrolytic copper) (78)

$K_m = -1.22 \times 10^{-6}$ (native copper) (76)

$= -0.086 \times 10^{-6}$ (electrolytic copper; Fe = 0.008 per cent) (80)

$= -0.085 \times 10^{-6}$ (electrolytic copper; Fe = 0.0004 per cent) (81)

The value of K may thus be taken as -0.085×10^{-6} for pure copper. The temperature coefficient of K is given by the equation (78).

$$\alpha_0 = -0.0015$$

that is, the value of K decreases with increase of temperature.

Cu_2O and CuO have been found to be paramagnetic. (75)

$$K_{(CuO)} = \text{about} + 20.0 \times 10^{-6}$$
$$K_{(Cu_2O)} = +0.62 \times 10^{-6}$$

2. THERMAL AND OPTICAL

(*a*) *Melting Point, Heat of Fusion, Boiling Point, Vapor Pressure.*—The *melting point* of copper is taken as 1083.0 deg. C., the value adopted by the Bureau (87) in standardization of pyrometers, etc. Small amounts of oxygen lower the melting point markedly; the melting point of the eutectic Cu-Cu_2O (3.45 per cent Cu_2O = 0.395 per cent oxygen) being about 1063 deg. C.

Richards-Frazier (105) give 43.3 calories as the *heat of fusion* of copper.

It has not been possible to determine the *boiling point* of copper accurately; this has been due largely to the experimental difficulties. Greenwood (83, 84) states that there is an interval of about 100 deg. C. between the temperature at which copper first begins to form bubbles and that temperature at which ebullition is vigorous. This latter temperature he gives as 2310 deg. C. at 760-mm. pressure, as measured with a Wanner optical pyrometer on electrolytic copper in an atmosphere of hydrogen, and states that it can readily be duplicated.

V. Wartenberg (87) states that the boiling point of copper lies above 2200 deg. C., and Féry (82) places it at 2100 deg. C.

Greenwood (84) also made three determinations of the vapor pressure of copper, his values being:

at 2310 deg. C., 1.0 atmosphere
2180 deg. C., 0.34 atmosphere
1980 deg. C., 0.13 atmosphere

From these data Johnson (85) has given the formula

$$\log p = 9.14 - \frac{16{,}400}{T}$$

p = vapor pressure in mm. of mercury.
T = absolute temperature.

This gives a pressure of 0.001 mm. at 1080 deg. C. From this formula it follows (Johnson, *loc. cit.*) that the heat of vaporization of copper is about 75,000 calories.

(*b*) *Thermal Conductivity.*—An empirical law, approximate only, of Wiedemann-Franz-Lorenz connects the thermal conductivity of pure metals with the electrical conductivity by the following relation:

$$\frac{\text{Thermal conductivity}}{\text{electrical conductivity}} = K \times (\text{absolute temperature})$$

Determination of both conductivities was made in 1900 at the Physikalish-Technische Reichsanstalt (90) on a "pure copper" (traces of iron and zinc, together less than 0.05 per cent). The results were as follows:

Electrical resistivity (18 deg. C.) = 0.01782 ohms (meter, mm.^{2}), conductivity of 96.8 per cent (international standard)

Temperature coefficient of electrical resistivity at 18 deg. C. = 0.00393

Thermal conductivity (18 deg. C.) = 3.73 $\frac{\text{watt seconds}}{\text{cm. second. degree}}$

Temperature coefficient of thermal conductivity = 1.96×10^{-4}

$$\text{Ratio}\left(\frac{\text{thermal conductivity}}{\text{electrical conductivity}}\right) = 665 \times 10^{-8} \text{ (18 deg. C.)}$$

Temperature coefficient of this ratio = 3.67×10^{-3}

Schaufelberger (92) obtained in 1902 a value of 0.9382 $\frac{\text{Calorie}}{\text{second. gram. degree. centigrade}}$ for "pure copper." The electrical conductivity of this material is however only 92.8 per cent, showing the material to be inferior in purity to that used by Jaeger and Dieselhorst.

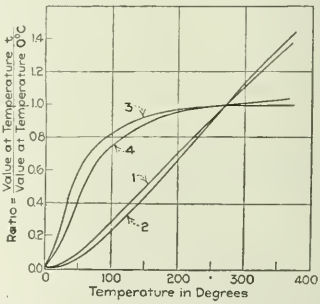

FIG. 12. THERMAL AND ELECTRICAL CONDUCTIVITY AT LOW AND HIGHER TEMPERATURE. (MEISSNER, 91)

Curve 1. $\lambda/\chi = \frac{\text{thermal}}{\text{electrical}}$ conductivity
Curve 2. $1/\chi$ = electrical resistivity.
Curve 3. $1/\lambda$ = thermal resistivity.
Curve 4. $\lambda/\chi T = \frac{\text{thermal conductivity.}}{\text{electrical conductivity} \times \text{abs. temperature.}}$
All quantities expressed as fraction of respective values at deg. C. The portion of curve between 0 deg. and 20 deg. abs. is extrapolated.

At lower temperatures, divergence from the Wiedemann-Franz-Lorenz law is still greater. The variation of the two conductivities and their ratio between 20 deg. and 400 deg. absolute is given by Meissner (91) in Fig. 12.

(*c*) *Thermal expansion.*—The linear thermal expansion of copper is not a linear function of the temperature but is well expressed (at least from —40 to +300 deg. C.) by a quadratic equation.

The thermal expansion of two samples of electrolytic copper furnished by the American Brass Co. has been determined at this bureau.

One sample was in the form of hot-rolled and cold-drawn trolley wire of N.E.C. copper wire-bar, of the following analysis:

	Per Cent		Per Cent
Copper	99.956	Nickel	.0001
Silver	.0005	Selenium	.0000
Iron	.0006	Tellurium	
Lead	.0007	Sulphur	.0017
Arsenic	.0025	Zinc	.0000
Antimony	.0011	Oxygen (diff.)	.0364

This sample showed between —24 deg. C. and +64 deg. C. a unit linear expansion, expressed (within 0.000003) by the following equation:

$$\frac{\Delta l}{l_0} = (16.48t + 0.00382t^2)\,10^{-6}$$

Another sample of electrolytic copper, battery assay 99.968 per cent Cu, hot-rolled, drawn and annealed, showed between — 49 deg. and + 305 deg. C. an expansion, expressed (within 0.000009) by the equation:

$$\frac{\Delta l}{l_0} = (16.34t + 0.00413t^2)\,10^{-6}$$

Dittenberger (95) gives the following equation for results determined between 0 deg. and 625 deg. C. on a sample of copper of "good conductivity":

$$\frac{\Delta l}{l_0} = (16.07t + 0.00403t^2)\,10^{-6}$$

Henning (96) has determined the expansion at low temperatures of the same material used by Dittenberger. He finds a contraction between 0 deg. C. and — 191 deg. C. of 2.917 mm. per 100 cm., which does not fit Dittenberger's formula.

Lindemann (97) finds Grüneisen's law, that the coefficient of thermal expansion / specific heat is a constant independent of the temperature, verified by determination

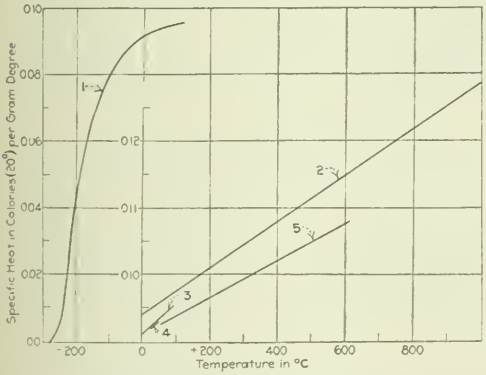

FIG. 13. EFFECT OF TEMPERATURE ON SPECIFIC HEAT (CONSTANT PRESSURE).

1. Nernst (102), electrolytic copper. Nernst & Lindemann (103) Keesom & Onnes (101).
2. Richards & Frazier (105).
3. Griffiths & Griffiths (99), electrolytic copper
4. D. R. Harper (100), electrolytic copper
5. Schübel (106).

of the expansion at low temperature. He finds

$\frac{1}{l}\frac{dl}{dt}$ from 85 deg. to 292 deg. (absolute) = 124 × 10^{-8}

20 deg. to 80 deg. (absolute) = 49 × 10^{-8}

80 deg. to 90 deg. (absolute) = 75 × 10^{-8}

(*d*) *Specific Heat.*—The specific heat of copper is *not constant* but varies with the temperature. In Fig. 13 are given curves taken from various observers indicating the effect of temperature on the specific heat.

The results of determinations made at the bureau (100) show that between 0 deg. and 50 deg. C. the specific heat of copper, 99.87 per cent pure, of 100.5 per cent electrical conductivity (Mattheissen Standard), is a linear function of the temperature, and may be represented by the formula

$$C = 0.0917 + 0.000048\,(t - 25) \text{ calorie 20 deg. / gram. degree}$$

This value agrees well with a probable value deducted from the results of many previous investigators.

Optical.—Copper is a metal, which takes a fairly high polish and reflects well. The reflecting power, the refractive and absorption indices are given by the curves

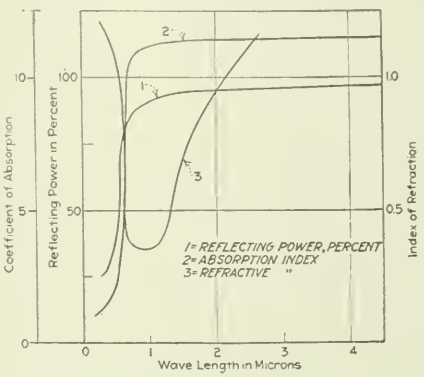

FIG. 14. OPTICAL CHARACTERISTICS OF COPPER

1. Reflecting power (perpendicular incidence) in per cent.

is clearly shown, the copper absorbing or emitting strongly at the blue end of the spectrum. According to Bidwell (107), Stubbs (114), and Burgess and Waltenberg there is no practical temperature variation of *Et* between 20 deg. and 1500 deg. C.

(*To be continued*)

Some General Aspects of Evaporation and Drying*

By HUGH K. MOORE

THE subject of Evaporation and Drying may be classified under six headings:

(1) Direct Evaporation or Single Effect (Pressure or Vacuum).

(2) Multiple Effect Evaporation.

(3) Air or Gas Drying.

(4) Radiant Heat Drying.

(5) Chemical Drying.

(6) Mechanical Drying.

The first is familiar to all of us, and is used, for instance, in boiling water in a teakettle or evaporating water as in the production of jelly or candy, etc., and is still done in the most primitive manner, namely, putting the substance into a sample shaped vessel and heating it by direct heat. In this we have the primitive steam boiler. The scope of this paper does not include either the history or the construction of the steam boiler, which was used as such by Hero, 150 B. C., for the production of power. We may, however, briefly consider the separation of two ingredients.

Direct Evaporation

Direct evaporation is used:

1. In cases where the amount of liquor is so small that it does not pay to have a multiple effect. An example of this is the evaporation of maple sap to make maple syrup, maple sugar, or candy, either under atmospheric pressure or vacuum.

2. In cases when the boiling points are so high that multiple-effect evaporation is not feasible; an example of this is the kettle process for caustic soda and caustic potash.

3. In cases where the liquor contains incrusting material, so that it is necessary to clean the tubes or pan very often. An example of this is the evaporation of salt brine containing calcium sulphate.

4. In cases where a certain sized crystal is desired. An example of this is the open drainer pan used in the salt industry.

5. In cases where the material to be evaporated is so corrosive that the materials required for the construction of the evaporator are too expensive to be used in anything but a single effect, of simple form. An example of this is to be found in the concentration of sulphuric acid, nitric acid, acetic acid, etc.

6. In cases where materials decompose at a high heat. Such an example is the production of concentrated coffee.

7. In cases where the object is to recover some volatile constituent. An example of this is the evaporation in the pot still. The evaporation in the column still is in this class, though it has certain features on the border line of the multiple effect.

8. In cases where the object is to obtain artificially a low temperature or a sudden chill. Both the absorption and compression systems of artificial refrigeration come in this class.

9. In cases either with or without vacuum, where the liquor to be evaporated is already a concentrated solution and its physical or chemical properties require that the final dried product be taken off as a film or powder or mass of crystals. Sulphite digester liquor is an example; this may be best handled in a rotary drum drier either with or without vacuum, according to the product one desires.

Direct evaporation in a vacuum is practised in nearly all the above cases, though not, as many persons seem to think, for economy of steam, but rather to secure the advantages of relatively low temperature. It is found that there is no great economy in direct evaporation under a vacuum over and above evaporation under atmospheric pressure, and none at all if the vacuum has to be produced by steam power.

Fig. 1 gives the values at different temperatures of the heat in a pound of water above 32 deg., the "latent" heat of vaporization, and the "total heat," or sum of the other two. Referring to Fig. 1, 1 lb. of steam at 212 deg. F. contains 1146 B.t.u. (above 32 deg.), while 1 lb. of steam at 134 deg., namely, under 25-in. vacuum, contains 1120 B.t.u. In other words, the pound of steam under 25-in. vacuum contains 97.73 per cent of the heat in a pound of steam at atmospheric pressure.

Multiple-Effect Evaporation

Multiple-effect evaporation is distinguished from single-effect in that the vapors evolved from a portion of the substance are condensed in a separated chamber by another portion of the substance, thereby giving up their latent heat to this other portion and liberating their equivalent in vapor from this other portion. Each such stage is called an effect. It will be seen that each effect acts simultaneously as a condenser and evaporator.

For instance, referring to Fig. 1, we find 1 lb. of steam at 242 deg. Fahr. contains 1161 B.t.u. in total heat, 950 B.t.u. in latent heat. Theoretically, if this steam heats water at 222 deg. Fahr., it should give up 971 B.t.u., evaporating thereby 1.007 lb. of water to steam at 222 deg. Fahr., having a total heat of 1154 B.t.u., and latent heat 964 B.t.u. per pound. This steam, in turn, could give an evaporation of 1.004 pounds of steam from water from and at 212 deg. Fahr. If we count also the available heat in the condensed water from the first effect we have 0.0103 lb. additional evaporation. In other words, in the double-effect operation as described we get 2.021 lb. of water separated from the liquor for 1 lb. of steam used. Now, the above figures are on a theoretical basis only. As a matter of actual practice, the evaporation in the above illustration would be a little lower, on account of the heat carried off in the drip, or condensed water, which would not be reduced quite to the temperature of the evaporated steam as was assumed in the illustration.

It will be seen that this operation can be repeated as many times as desired, provided only that a tempera-

ture difference is maintained between successive effects.

This, in brief, is the principle of multiple-effect evaporation. Later on in this paper the writer will explain a few of the intricacies of such evaporation.

The multiple-effect principle is used:

1. Where the amount of liquor to be evaporated is large.

2. Where the cost or concentration of the valuable ingredients is so small and the cost of fuel is so high that the evaporating cost is an appreciable item in the whole operation. As a matter of fact, multiple-effect evaporation is very seldom resorted to on a small scale, because the required constant attention of an expert evaporator man usually more than offsets the saving in fuel. Furthermore, the first cost of a small multiple-effect evaporator is all out of proportion to the work done.

Air Drying or Gas Drying

Air (or gas) drying is a method of evaporation in which the partial pressure of the vapor of the volatile constituent is kept less than the vapor pressure of the liquid by mixing with the vapor air, or other gas. In this case the pressure shown by a gage is the total pressure, or sum of the partial pressures of vapor and air.

Women know that they can dry clothes on a fine day even though the temperature be below freezing. They can also tell you that if the wind is blowing briskly the clothes will dry much more quickly. Here, then, you have a common case of air drying with which every one is familiar, though few could tell how it is possible. The curves on Figs. 2 and 3 show the vacuum required to produce boiling compared with maximum per cent water vapor in air at the same temperature. On this chart will also be found the relation to temperature. Thus, air at 187 deg. will take up additional water only if it contains less than 60 per cent by volume of water vapor, and water at 187 deg. boils only if a vacuum of 12 in. is exceeded. Then at 187 deg. air containing 60 per cent water vapor may be said to correspond to a 12-in. vacuum. At 195 deg., air containing 60 per cent *by weight* of water vapor corresponds to a 9-in. vacuum. Again, saturated air containing 10 per cent water by volume corresponds in temperature to 27 in. of vacuum (115 deg.). It will thus be seen that by decreasing the proportion of water vapor in the air the temperature effects of any desired vacuum can be obtained without the necessity of maintaining a real vacuum in a closed apparatus. A given volume of air, if maintained at a given temperature, can only evaporate a certain maximum amount of water (or other fluid), and this limit is only approached when the air has been brought into intimate contact with the substance to be evaporated,

FIG. 8

so that all parts become saturated. Of course, it goes without saying that the hotter the air and the drier the air the more rapid the evaporation. However, increasing the temperature of the air does not increase the temperature of the wet substance very greatly if the percentage of saturation is kept low enough. One pound of water requires about 1000 B.t.u. for its vaporization, whether it be evaporated under pressure or in a vacuum. Now, in every case the necessary heat must be supplied, either from the air, from the substance being evaporated, or by conduction to the substance being evaporated. It should be remembered that heat is relative, and things we consider cold may give up heat to things which are colder. It may be asked where the heat comes from that evaporates the water in clothes hung out to dry on a cold winter day, and what difference of temperature there could be. Perhaps this can be answered graphically by the curve of Fig. 4, which shows the cooling effect of dry air, based on wet and dry bulb-thermometer readings; also Fig. 5, showing pounds of dry air required to furnish heat to evaporate 1 lb. of water at various temperatures. Fig. 6 shows pounds of water per pound of air and pounds of water per pound of mixture when air is saturated at different temperatures. For example, Fig. 4 shows that with dry winter air at 30 deg. F., the clothes could drop to a temperature of 20 deg.. and Fig. 5 shows that 470 lb. of dry air at 30 deg. would contain enough available heat to evaporate 1 lb. of water at 20 deg. Fahr. This assumes that the air is originally dry, and leaves saturated. If, however, the air is not dry, and does not leave saturated, a greater quantity is required. It will be seen that in this case the air furnishes the requisite heat for the evaporation. As a brisk wind moves a greater quantity of air past the wet surface, it will readily be seen that the evaporation must necessarily be more rapid. The temperature of the wet clothes will depend on the saturation and temperature of the air, but cannot go below the values of Fig. 4. Here in a simple illustration are all the fundamental principles of air drying.

The writer has been asked why we cannot take a sufficient quantity of air and dispense with artificial heat. We can, but if it costs more for apparatus and power to move and utilize this air than it would cost to supply the required heat we have gained nothing, and perhaps have the additional expense of conditioning or filtering the larger quantity of air.

From the above it will be seen that while air drying at an elevated temperature partakes in some respects of the advantages of vacuum drying, it may not be as economical in the expenditure of heat, inasmuch as heat has to be supplied to raise the temperature of the air, as well as to furnish heat for the evaporation of water (or other fluid).

Having briefly touched on the principles of air drying, let us see under what conditions it may be profitably employed:

1. The drying, at relatively low temperature, of a substance which is continually entering and leaving the apparatus. In this case it would be practically impossible to obtain a vacuum. An example of this is the drying of pulp, paper, cloth, etc., over hot rolls. Heat is supplied to the rolls, and the hot, moist sheet, leaving the rolls, passes through the air and is dried. The rapid evaporation keeps the temperature down to such a limit that the pulp or paper is not seriously affected by the heat. Here, continuity of process and nature and amount of the materials are the controlling factors.

2. The drying, at low temperatures, of substances whose internal structure must be preserved. Examples are eggs, wood, pulp, pipe, etc. In the first example, for instance, if eggs were evaporated in a vacuum, one would have an edible product; but owing to the rapid evolution of steam from the interior as well as the surface, the organic structure would be so destroyed that one could not make an omelet from the resulting product; while if the eggs are air dried by letting this moisture gradually diffuse to the surface, the resulting product can be beaten up and a fine omelet can be obtained. The drying of wood in such a manner as to avoid checking is a more familiar illustration, and need not be gone into here.

3. Where the final product must be in a fine state of subdivision, and heating, even for a short time, may destroy some valuable characteristics.

An illustration is the evaporation of milk to milk powder and eggs to egg powder; these substances cannot be kept even momentarily at a high temperature during evaporation without altering or coagulating. Here the milk or eggs are reduced to such fine particles that they are nearly all surface. When these particles come in contact with hot, dry air they part rapidly with their water, and this rapid evaporation prevents their reaching too high a temperature.

Mr. O. G. Soule of Merrill-Soule has kindly furnished me with the following information as to the evaporation and drying of milk:

The milk is first condensed in a vacuum pan until it contains approximately 33 per cent solids. This is done for two reasons: First, it is a cheaper method of evaporation than evaporation entirely by spraying into the air; secondly, the resultant product, when finally dried, has what is called a greater apparent specific gravity; that is, the powder is more compact, and in an equal volume will have a greater weight than the product obtained entirely by the air spraying. After evaporation under vacuum to 36 per cent solids, the product is sprayed—under pressure of between 3000 and 4000 lb. to the square inch—through a minute orifice, with the result that the milk is subdivided into very fine spheres. This product is sprayed into a drying chamber through which is passed a current of air heated to approximately 180 deg. Fahr. The small particles of the liquid are thus entirely suspended in this current of air in the shape of minute spheres, representing an enormous surface, and resulting in very rapid evaporation. The product, as it dries, falls to the bottom of the drying chamber, or is carried along with the current of air and collected outside the drying chamber by means of a dust collector of special design. Since evaporation takes place in the air entirely, the particle being evaporated is kept cool during the evaporation; while if evaporation takes place in contact with a heated metal surface the product, during evaporation, is itself heated, and the albumin of the milk tends to coagulate. In the Merrill-Soule method of drying, this cooling effect is obtained, and the product does not become heated until the moisture is substantially removed. The advantage of this is apparent from the fact that neither the vitamines nor the enzymes are materially injured by this process; neither is the albumin coagulated. When the milk powder is reconstituted with water they find the original bacteria becoming active, the enzyme action apparently unchanged, and the growth-promoting qualities still in their original form. This, so far as they are aware, is a result unobtainable in any other way. While the milk powder is in its dry state there is found no material action taking place on account of the bacteria therein. The bacteria do not multiply, but rather tend to decrease in the product due to the absence of moisture. On the other hand, when moisture is put back into the powder the bacterial action goes on as in the original milk, and a similar fermentation takes place as takes place in milk.

A similar process is also applied to the drying of eggs; the egg albumin is not coagulated, and is soluble in cold water.

As a matter of commercial practice, milk is pasteurized before drying, thus killing pathogenic bacteria, and practically the only bacteria left in the powder are of the lactic acid variety, which are, of course, harmless or useful.

4. Drying such substances as are not affected by heat, but are either sticky or poor conductors of heat.

Such, for example, is the process used in drying salt, lime sludge, or the black liquor made by the soda and the so-called sulphate processes for wood pulp. In the latter case, water is not only evaporated, but the residue is also charred so that it loses its sticky qualities; but as the object is the recovery of the soda base, this does no harm.

Drying by Means of Radiant Heat

The writer discussed radiant-heat drying at considerable length in a previous paper before this society,* and so has no need to go into it here; neither is the time at his disposal sufficient to warrant its discussion at this time.

Suffice to say that probably in the near future it will be used in concentrating many substances which require a high temperature for evaporation and where there is no suitable material of which to construct the types of apparatus now in use. It is now used for the evaporation of the so-called sulphate black liquor. It is thought that this process offers a great opportunity to solve the difficulties encountered in connection with the phosphoric acids.

Chemical Drying

The ability of certain chemicals to absorb water or other fluids is made use of in drying many substances, and the principles are so well known to the chemical engineers that we can dismiss the subject by giving a few illustrations. These fall into a natural classification according as the wet material is a gas, a liquid, or a solid.

1. Undoubtedly the most use is made of this principle

*See this journal Aug. 1, 1917, p. 117.

in drying gases. Here we have two vapors mixed which it is desired to separate. This mixture of gases is passed through a chemical which absorbs one and allows the other to pass through unchanged. Thus in the hydrogenation of oil, dry hydrogen is required. In this case the wet hydrogen is passed through concentrated sulphuric acid, where the moisture is absorbed. Most wet gases attack pipes of the ordinary materials, but if they are dried few if any have any action whatsoever. Chlorine, sulphur dioxide, hydrochloric acid gas, hydrogen, and hydrogen sulphide are examples of gas which are handled in large quantities in this manner.

2. Liquids are sometimes dried in the same manner as gases. An emulsion of oil and water may be separated by hydrochloric-acid gas. Mineral oils are dried by the use of sulphuric acid, and in cases where a trace of acid must not be left they are dried by the use of calcium carbide. In either case the oil comes out more or less dry. Chloroform is dried over calcium chloride or zinc chloride, as well as sulphuric acid.

3. Solids may be dried either by contact with an appropriate gas or by immersing in a volatile liquid, which, uniting with the substance to be removed, will pass off easily at a much reduced temperature. As an illustration of the first method we may take the drying of crystallized magnesium chloride. In ordinary evaporation this would break up into magnesium oxide and hydrochloric acid, but if dry hydrochloric acid gas is passed through it under pressure the drying will be accomplished and the decomposition largely prevented. Or again, according to the second method, magnesium chloride may be dried to the decomposition point and then mixed with amyl alcohol and the mixture evaporated. In this case, very little decomposition takes place if the amyl alcohol is in sufficient excess and the operation is done in a vacuum.

Again, butter fats may be dissolved from their water and other admixture by dissolving in deodorized rhigolene or cymogene and evaporating the solvent at a low temperature.

Mechanical Drying

This hardly comes within the scope of this paper, and will be dismissed by classifying and giving a few illustrations. Five fairly common means might be distinguished: 1, squeezing; 2, filtering; 3, centrifugal force; 4, heating; 5, refrigerating.

1. The hydrostatic press may be used to dry wet materials, as, for instance, in pressing the water from wood pulp, oils and water from seeds, and water from fabrics. The compression of a saturated gas reduces its capacity to hold water vapor at the same temperature, and effects a partial drying.

2. Filtering may be illustrated by the separation of lime sludge from caustic liquor in a filter press.

3. The centrifugal machine in most cases is simply a filter in which centrifugal force is substituted for hydrostatic pressure, though in some cases the centrifugal force is so applied that it merely accelerates the natural separation of two materials of different specific gravities.

As a filter, the centrifugal machine is used most in separating crystals from a mother liquor. Thus: in separation of salt crystals from caustic solutions, or sugar from its mother liquor.

Centrifugals are used in the other manner in separating oil from water, or in separating an emulsion of cotton-seed oil, water and soaps of the fatty acids; or in separating the oil emulsions encountered in steam-power plants.

4. Air at its dew point may be dried in the physical sense by heating it. This is done in heating ventilation, etc. Of course, chemically there is just as much water in the air after heating as before heating, and this is only a case of apparent drying.

5. Conversely, air may be caused to give up its moisture by refrigerating. This principle is made use of in the dry-blast process in the production of iron and steel. Sometimes a gas may form a compound with water, or other substance to be removed, and may be used to dry itself. Thus, if liquid chlorine is sprayed through moist chlorine gas, or liquid sulphur dioxide through moist sulphur dioxide gas, the liquid will vaporize, abstracting heat from water and gas, and the water will be precipitated in solid form in more or less loose combination with the chlorine or sulphur dioxide, as the case may happen to be.

Heat Conductivity Data

The subject of evaporation and drying, in the sense as used by chemical engineers, is indissolubly connected with the subject of condensation and the heat conductivity of the materials used in the construction of apparatus.

The data used for conductivity through the metal partitions, which we are interested in when it comes to the designing of an evaporator, is not the thermal conductivity of metals, as given by physicists, as the conditions are not the same as those under which the physicists obtained their data. For instance, the heat conductivity of copper is given as 500, that of iron 233, and that of lead 103, all in B.t.u. per square foot per inch thickness per degree Fahrenheit difference per hour. Now, as a matter of fact, this data is of very little use, if any, to the engineer who has the problem of designing an evaporator for a liquid of given properties. If you have an evaporator with iron tubes, in which water and steam are the fluids on the two surfaces of the partition, you will get a conductivity of from 200 to 250 B.t.u. during the first stages of the heating; but during the second stage, that is, when ebullition becomes rapid, the conductivity increases to 1000. Now, the iron has not changed in the slightest degree, but the latter apparent conductivity is from four to five times as great, showing that we must look for some other factor than the conductivity of the metal alone. The factor in this case is the movement of the molecules of water. Water not in motion is a very poor conductor of heat, but when new molecules are brought in contact with the heated surface the absorption of heat from the heated surface is very much increased. Practically speaking, then, the large factor of conductivity in this case is not the metal but the rate at which heat is conducted from the surface of the metal to the liquid, and this factor may be expressed in terms of velocity of the liquid. The writer has obtained a conductivity of 1200 B.t.u. per square foot per degree Fahrenheit difference per hour through lead pipe by increasing the velocity of the liquid flowing through it. Under these same conditions, copper tube did not increase the conductivity more than could be accounted for by experimental error. Iron may have an apparent

conductivity of 200 to 250 B.t.u. to water not in motion, but if melted sulphur is substituted for the water the apparent conductivity drops to 3 B.t.u. A familiar case of the above is an ordinary boiler tube, which, having air on one side and water on the other, may not conduct more than 3 to 6 B.t.u. per degree difference Fahrenheit. Also a horizontal tube with water on the outside and steam on the inside will not have the apparent conductivity if it is 10 ft. long that it has if it is 3 ft. long. Here the determining factor is the length of the tube. As the steam condenses we have an accumulation of water on the bottom of the tube, and the depth of this increases as the length; since water itself is a poor conductor, and is not in this case in rapid circulation, it does not transmit heat readily to the tube. In the case of vertical tubes, in which the liquor is on the inside, there may be varying factors. The diameter may or may not be an influential factor. As you increase the length of the tube you tend to increase the velocity of the fluid inside the tube. This tendency to increase the velocity is due to the increase of the unbalanced pressure between relatively cool bodies of liquor in other parts of the bath and the warmer column of liquid and vapor circulating upward through the tube. This acts in much the same way as increasing the height of a chimney increases the velocity of the hot gases in the chimney. The effect of increased height may be offset, however, by an increase in the diameter of the tube, since in tubes of equal length the surface increases as the diameter, while the volume increases as the square of the diameter. It can readily be seen that the volume is so increased by increasing the diameter that the increase in heating surface is more than counterbalanced by the increase in weight of the liquor to be heated. See Fig. 7 and Fig. 8. This is what happens in the large central tube in some evaporators, or the outside zone in other evaporators, a downward instead of an upward current being maintained. An increase in the height of a tube may not always increase the heat conductivity. If the diameter be so small and the length so great that all the liquor entering it is transformed into steam, then an increase of height will be a detriment.

Brown Co., Berlin, N. H.

(To be continued)

Symposium on Potash

A joint meeting of the New York Sections of the American Institute of Mining Engineers and the American Electrochemical Society was held on Jan. 24, at which qualified speakers reviewed our various resources and gave the status of industries now contributing to our potash needs. The speakers and their topics were as follows: Col. Allerton S. Cushman, Frankford Arsenal, Philadelphia, and Alfred H. Cowles, Potash from Silicate Rocks; Dr. Wm. H. Ross, Department of Agriculture, Washington, Potash from Kelp; Leslie H. Webb, Western Precipitation Co., Philadelphia, Potash from Cement-Kiln and Blast-Furnace Dust; Sidney J. Jennings, Potash from Alunite; Kirby Thomas, Potash from Saline Lakes; E. G. Spillsbury, Potash from Greensand. Production from all sources in 1917 may amount to between 15,000 and 17,000 tons in terms of 80 per cent KCl. Cement-kiln dust is a promising source and may yield 70,000 tons per annum.

The Effect of the War on Engineering Education

By C. R. Mann

THREE years ago most of us thought that a world war could not last long because, however much kings and kaisers might wish to continue, the banker would stop it. But the financiers have not come up to our expectations in this matter, and we have therefore been compelled, unwillingly perhaps, to recognize that money is not the ultimate measure of national strength. National credit is the result and not the cause of intelligent industrial production; the engineer, not the banker, is the real power behind the throne.

This fundamental fact now seems so simple and self-evident that it is rather hard to remember the time when we thought otherwise. But though the rugged outlines of this fact are now sharply silhouetted against the ruddy dawn of the new age, the details of its meaning are but dimly discernible through the haze of speculation over the significance of the struggle. Naturally the engineer is intensely interested in the development of the details of the picture, for on him devolves the duty of interpreting the coming conceptions in terms of materials and organizations of men. And if education makes men, engineering education must be the first to feel the thrill of the dawning day.

Three elements in the picture can now be plainly perceived. These indicate that the engineer is from henceforth vitally involved in the control of credit, in the interpretation of the daily news, and in the organization of industry and commerce to make goods cheap and men dear.

In performing the first of these new functions, the engineer becomes the partner of the banker to determine which projects are worthy of financial support and which not. As the engineering spirit is more and more infused into this dispensing of credit, public service rather than excess profit becomes the inspiration for enterprise; intelligence in production becomes the best security for loans; ability to deliver the goods becomes the sure basis of financial success; and the control of tools gradually passes from the hands of those who own them legally into the hands of those who can use them effectively.

Newspapers and periodicals already sense the expansion of the engineering spirit in the struggle to make the nation strong. The distribution of wheat, the supply of sugar, the transportation of coal and the price of bread are now subjects which occupy an amount of space in the daily press that only a Thaw trial could formerly command. The public has never before realized how vital and how interesting factories, freight cars, warehouses, terminals, trucks and ships really are. Some faint conception of the necessity of organization for the common project of liberating life by winning the war seems to be taking shape; while an impelling desire to serve and to subordinate personal preferences to community interests appears to be dimly developing. These faint feelings of fraternity may grow into driving impulses, if editors continue to extol engineering enterprise rather than private profit in their interpretations of the daily news.

In many communities chambers of commerce or groups of engineers have organized to build up business

and boom the town. Through their efforts living conditions have been improved and many a city is being made a better place for homes. But the progress has always been hampered by the vested rights of individuals and of corporations, so that none has yet dared to envisage an entire community as a single working plant for the purpose of organizing it for the most intelligent production of human wealth. This can now be done. The war is opening many hitherto blind eyes to see that each gains more than he loses when he merges his strength with the might of all in an organization that is constructed for the purpose of releasing creative energy by giving each the work he is best qualified to do.

The time has come for such an organization in every community and every state, because the Federal Government is struggling to shape the nation into an organization of this type. Only so may the nation be strong; only so may communities add their utmost to the nation's strength. The responsibility for this work must finally be shouldered by engineers who are both masters of the mechanic arts and moulders of men.

For many years this country has been drifting toward the realization of these requirements. The war has but accelerated the process and precipitated conclusions that were bound to come, otherwise men trained by experience to meet the present crisis could not now be found. Continuity demands that the same conclusions remain valid long after the war is ended. Therefore, engineering schools will render service in proportion as they grasp the implications of these conclusions and express them in the work of instruction.

The possible conclusions for engineering education are many and complex; but two stand out in bold relief, namely, there must be closer co-operation between school and industry, and there must be more attention to the appraisement of values and costs.

The essential feature of the co-operation with industry is not the skill, the knowledge of workmen, or the feel of the machines which the student acquires from shop experience. Important as these are, they cannot compete with the spirit of investigation which must develop if the co-operation between school and industry is real and vital. There are thousands of unsolved problems in even such rough shop work as freshmen are permitted to do. The boy should be trained to discover these unsolved problems and to bring them back to school for discussion and solution. By making shop work in industrial plants the source of problems for solution in school, and by relating the class and the laboratory work in some degree to the problems raised, conditions most favorable to the self-development of the student may be realized. As he progresses, the problems become more and more intricate, until in his last year, if he has shown real engineering ability, he may be assigned as helper in industrial research, either at the plant or in the school laboratories. After such a training in defining and solving problems, closely co-ordinated with instruction in science and drill in mathematics, he should be able on graduation to take a responsible position without serving several years as an apprentice, as is usual at present.

To the faculty this type of co-operation with industry brings incentives for creative work in production and in education. For co-operation makes the school the source of solutions of industrial problems, not only with respect to the technique of manufacture, but also concerning the correlation of the community's productive processes with the training of its citizens as intelligent workers. Hitherto manufacturing companies have stood aloof and regarded one another with suspicion—and the Federal Trade Commission discovered that 200,000 of them are not paying expenses; but now they are ready to co-operate. Similarly in education, many manufacturers are supporting corporation schools to train their own help, while more than half the children in the entire country quit school at the sixth grade without being trained to earn a living, but they too are now ready to co-operate. If the men who are teaching in engineering schools rise to the responsibility and organize for the systematic study of community production, they could soon create a true university, with its feet firmly planted in industry and its soul consecrated to the task of utilizing science and literature to liberate the creative energies of men.

While close co-operation between school and industry gives that practical experience which is essential for mastery of the mechanic arts, it is not in itself sufficient to enable the schools to meet adequately the fundamental requirements of engineering in the new epoch. The Germans are technically well trained in the mechanic arts, yet they are but brutally strong. In order to strengthen the nation by infusing the engineering spirit in the control of credit, in the interpretation of the daily news and in the organization of industry for the production of human wealth, the engineer must have sound judgment in the appraisement of values and costs. This requires not only an understanding of finance and the meaning of money, but also a sympathetic appreciation of the things humanity holds to be most worth while. Even a practical project like building a bridge is ultimately controlled by some man's decision that the resulting value is worth the cost; and this decision is more difficult and subtle when it concerns profoundly the production of human wealth and the appraisement of human values and costs. The engineer is too often obliged to be only the employee of the bank, the corporation, or the state commission, because he believed that engineering is wholly a matter of technical skill; when control in this, as in everything else, is really vested in the decision of the question whether the game is worth the candle.

Training in the appraisement of values and costs does not require the addition of formal courses for that purpose, but rather the injection of this point of view into every branch of school work. For example, experiments in chemistry need not always be of the type: Analyze this baking powder. The project: Make baking powder and find out if it is cheaper and better than any you can buy, is vastly more effective as a training exercise. Presented as a personal effort to appraise the human values and costs in life's experiences, literature fascinates engineering students. Economics delight them when it is a critique of proposed solutions of the social problems defined by their daily co-operation with labor. Such exercises also foster the development of those homely virtues, which always make the working people the bulwark of a nation's strength—the sense of justice, feelings of neighborly kindliness, devotion to right, and respect for God and man.

New York, N. Y.

Recovery of Spelter and the Treatment of Retort Residues

By EDWARD MACKAY JOHNSON

Supt., Henryetta Plant, Eagle-Picher Lead Co.

IT IS customary at nearly all zinc smelters to make three draws of metal. The proportion drawn at each time is approximately as follows:

Smelting 50% Western Sulphide + 50% Leadville Calamine

	Charge	Blue Powder	Total
1st draw	22.7%	15.1%	37.8%
2d Draw	36.5	18.6	55.1
3d Draw	0.6	6.5	7.1
	59.8	40.2	100.0

Smelting Concentrates from Colorado Ore

	Charge	Blue Powder	Total
1st Draw	27.6%	10.2%	37.8%
2d Draw	35.2	15.0	50.2
3d Draw	5.0	7.0	12.0
	67.8	32.2	100.0

Smelting ⅔ Joplin Ore + ⅓ Leadville Calamine

	Charge	Blue Powder	Total
1st Draw	27.4%	10.8%	38.2%
2d Draw	34.4	14.5	48.9
3d Draw	6.3	6.6	12.9
	68.1	31.9	100.0

Smelting Straight Joplin Ore, Making Four Draws

	Charge and Blue Powder
1st Draw	20% 2 top and 2 bottom rows
2d Draw	32% whole furnace.
3d Draw	39% whole furnace.
4th Draw	9% whole furnace.

After establishing the percentage of each draw, giving the best recovery for a particular ore, the fireman may be instructed to so bring his furnace; but, as a rule, the proportion of metal drawn in no way controls the firing of the furnace.

Composition of Spelter.—Iron and lead are nearly always determined in the spelter, as they practically control its classification. Cadmium is occasionally required.

The following results on spelter made at different plants give some idea as to the per cent of these elements existing in the zinc, and shows the reduction in quantity of iron and lead in the spelter by the use of a front charge, either of coal or an ore low in iron and lead, the front charge being charged in the mouth of the retort. This, of course, increases the cost per ton.

Smelting a Colorado ore high in iron, and using the front charge, the following results were obtained:

1st Draw Charge		2d Draw Charge		1st Draw Blue Powder		2d Draw Blue Powder		3d Draw	
Fe%	Pb%	Fe%	Pb%	Fe%	Pb%	Fe%	Pb%	Fe%	Pb%
0.032	1.09	0.132	1.50	0.064	0.83	0.088	1.48		
0.016	1.03	0.110	1.60	0.050	0.92	0.080	1.48	0.37	2.18
0.020	1.09	0.076	1.59	0.06	0.97	0.072	1.39		

The general average, exclusive of third draw, would be Fe = 0.055 per cent, Pb = 1.20 per cent.

Smelting Joplin and carbonate ores low in Fe, with no front charge, all draws averaged Fe = 0.042 per cent, and Pb = 1.41 per cent.

Smelting a high iron ore with front charge, all draws average Fe = 0.061 per cent, and Pb = 1.31 per cent.

	Average 2d Draw Fe%
Not using front charge 4 days	0.089
Using a front charge 8 days	0.055
Reduction due to use of front charge	0.034

Smelting Joplin ore, average of charge and blue powder:

	Pb%		Pb%
1st Draw, 2 top rows	0.64	2 bottom rows	0.70
2d Draw, 2 top rows	0.88	2 bottom rows	0.79
3d Draw 2 top rows	1.13	2 bottom rows	1.00
	0.88		0.83

Brass Special.—In using ores low in iron and lead it is sometimes possible to separate the first-draw charge and blue powder from the other draws, provided it does not make the latter too high in iron and lead. Spelter of the following analyses would probably pass for brass special: Fe, 0.03 per cent; Pb, 0.65 per cent; Cd 0.30 per cent.

Sampling Spelter

In order to obtain a sample representative of a lot or car of spelter a certain number of plates from each draw should be drilled and the drillings mixed, each draw to itself. Then from these samples aliquot parts (representing the weights of each draw in the lot or car) are thoroughly mixed, from which no less than 20 grams should be taken for a sample.

Granulated Sample

Many of the plants are now having the fireman of the block take a small sample of the molten zinc from one or two ladles of each draw, just before molding. This should be poured from a height of several feet in as small a stream as possible, into a clean bucket containing clean water. The water is decanted off, the sample dried and transferred immediately to a clean pan or sack.

Such a sample will go into solution very rapidly, which is a decided advantage in controlling the iron and lead in the spelter. In taking a granulated sample, the chance of "salting" from the steel drill is also removed. The following test illustrates this: While the metal drawer at one of the plants was molding a plate of zinc the writer took thirteen samples from the stream. The plate was then drilled in thirteen places and all the samples were analyzed for Fe. The comparison is given in the accompanying table.

Controversies often arise between the producers and consumers of spelter with respect to the iron contents. In certain cases this may be due to "salting," but it is more apt to be due to the fact that four or even six draws, each with a different analysis in iron and lead, may be loaded into a car or piled into one lot for ship

Comparison of Analytical Results

No.	Percentage Iron—Drilled	Percentage Iron—Granulated
1	.084	.084
2	.048	.058
3	.122	.068
4	.110	.104
5	.072	.080
6	.096	.068
7	.072	.070
8	.104	.082
9	.062	.094
10	.068	.078
11	.094	.080
12	.084	.068
13	.084	.058
Average	.082	.077

ment. It would therefore be impossible for the buyer to obtain an accurate sample unless he sampled every plate, making a composite sample of all. It is interesting to note that while the third draw is only about 10 per cent of the total metal produced, it may actually contain as high as 50 per cent of the total iron in the spelter, and a large proportion of the total lead, as will be seen from the following example. Assuming 100 lb. of spelter produced, we have the following results:

	Total lb.	Percentage Fe	Percentage Pb	Pounds Fe	Pounds Pb
Draws exclusive of 3d Draw	90	0.055	1.20	0.050	1.080
3d Draw	10	0.350	2.18	0.035	0.218

Treatment of Retort Residues

General.—In view of the fact that a considerable proportion of the ores treated at the spelter works (primarily for the extraction of zinc) carry silver, gold, lead and copper, either singly or in various combinations, the proper method of handling the residues is one of considerable importance, and will probably be given more attention in the future than in the past.

The method of treating the residues not only varies at the different plants, but sometimes at the same plant, according to conditions and the analysis of the material. Whenever the residue is of such a value as to overcome the treatment charge, freight, etc., and leave a fair net profit per ton, it will, as a rule, pay better to ship direct without any attempt at concentration. If the residue, however, is too low in value to show any profit on direct shipment, some of the following means of concentration may be and are often adopted: dry screening, jigging, burning, smelting.

Dry Screening

This is the simplest and cheapest method of concentrating the residues, and often gives a very good grade of concentrate without much loss, provided the screen openings are not too fine. Under ordinary conditions a screen of No. 16 wire having 5 or 6 meshes to the linear inch is as fine as should be used. This size will remove only the clean, coarse coal or coke, provided the residue and fuel have in no way been sintered together during the process of extracting the zinc, or by permitting them to become wet or oxidized previous to screening. In either of the latter cases it would not pay to screen.

As previously stated, when the residue shows a direct profit it seldom pays to screen. A possible exception to this is where the lead runs just below 5 per cent, and is paid for as iron excess, or 10c. per unit. By screening through a screen just coarse enough the lead may be brought slightly above 5 per cent, and then be worth about 30c. per unit. Again, the lead in the blue powder residue will, as a rule, run as high as the lead in the charge residue. It may, therefore, occasionally pay to screen the blue powder residue and mix it with the charge residue.

Miscellaneous Screen Tests

No. 1

Using a 3-mesh screen 7/32-in. opening

Charge Residue

Mesh	Weight Lb.	Weight Tons	Per Cent	Analysis SiO2	Fe	Zn	S	Pb	Ag	Au	Gross Value	Treatment, Freight, Etc.	Net Value
Charge Residue													
Plus 3	3819	1.91	32.3	13.3	10.0	6.0	3.8	2.5	7.8	0.16	$7.04	$5.70	−$1.34
Minus 3	8025	4.01	67.7	10.6	13.4	10.0	5.5	7.21	1.7	0.27	13 91	5.70	− 8.21
		5 92	Crude Residue=72%								$11.69	$5.70	$5 99
Blue Powder Residue													
Plus 3	1617	0 81	35.2	18.0	7.4	6.2	2.1	2.2	3.7	0.09	$2.80	$5.70	−$2 90
Minus 3	3008	1.50	64.8	11.1	9.4	8.7	3.8	6.2	6.7	0 14	8.16	5.70	+ 2 46
	4625	2 3	Crude blue powder residue=28%								$6.31	$5.70	$0.61

From the above figures it is apparent that it would not pay to screen the charge residue, while it would pay to screen the blue powder residue, as illustrated below:

2.3 tons per day per block at $0.61	$1.40
1.5 tons per day per block at 2.46	3.69
Difference per day	$2.29
On a 5-block plant per month	$345.00

The screening may be done by hand, but can be accomplished cheaper mechanically.

No. 2

Using a screen of 5-Mesh No. 15 Wire

Analysis

	%	Ins.	SiO_2	Fe	Zn	Pb	Ag
Crude residue	100	27.5	18.0	20.9	4.0	6.1	10.5
Plus 5 mesh	26	32.8	22.8	14.8	2.8	3.4	7.0
Minus 5 mesh	74	25.4	15.0	22.2	4.5	7.0	12.0

No. 3

Using a screen of 5-Mesh No. 15 Wire

Crude residue	100.0	...	13.7	24.0	7.2	6.5	10.9
Plus 5 mesh	31.3	...	16.6	12.2	4.9	2.7	4.8
Minus 5 mesh	68.7	...	12 0	28.0	7.7	7.1	12.4

No. 4

Using a screen of 5-Mesh No. 16 Wire

Crude residue	100	...	13.8	24.7	7.0	2.5	10.4
Plus 5 mesh	36	...	15.0	15.2	5.0	1.8	6.3
Minus 5 mesh	64	...	13.0	30.0	8.0	3.0	12 8

No. 5

Using a screen of 6-Mesh No. 16 Wire

Crude residue	100	...	15.0	19.8	6.6	2.0	7.7
Plus 6 mesh	47	...	16.8	10.9	5.4	1.5	3.5
Minus 6	53	...	13.3	27.6	7.6	2.5	11.4

From such data as the above it is a simple matter to calculate the advisability of screening, and some idea is gained as to the screen best adapted, provided the results warrant the operation. The percentages on and through the screen, indicated as plus and minus, vary somewhat according to the degree of fineness of the charge fuel used in the furnace. In fact, the size of the charge fuel really governs the size of the screen opening.

Jigging Residues

Several plants have tried out the Harz type of jig on residues, but the success is very doubtful. At least the method has gone out of use at the plants of this country so far as the knowledge of the writer goes. One company has also tried out the Hancock jig, but judging from results, and records of the writer, and the fact that the method has not become adopted, it can hardly be considered satisfactory.

The results here submitted might be materially improved by the use of an automatic feed to the jig, and the further concentration of No. 4 hutch in some manner. Where the residue has been permitted to weather and oxidize, it is even still harder to effect a good separation. The first residue direct from the furnace gives a good grade of concentrate, but, due to the intimate mixture of the heavy fine slate in the coal and the fine ore, there is too much loss in the tailing. While the following results are not conclusive they give an indication of what may be expected.

The plant was designed and built to handle 100 tons per day, and consisted of the following equipment:

1 54-in., 80-hp. boiler.
1 52-in., 80-hp. boiler.
1 14-in. Blake crusher, 300 r.p.m.
1 set of rolls, 16 in. by 14 in.
1 main elevator to screen.
1 revolving trommel, 34 in. by 6 ft., with 6-mesh No. 16 wire, 18 r.p.m.
1 No. 4 centrifugal pump, 900 r.p.m.
1 4-compartment Hancock jig, 190 strokes per minute, ¼ in. vertically and 3/16 in. laterally, with following screen dimensions:
Hutch No. 1, 39¾ in. by 2 ft.
Hutch No. 2, 41¾ in. by 2 ft.
Hutch No. 3, 33 in. by 2 ft.

In addition to the above, a small Harz jig was later installed, with a view of separating the coal from the slate by handling the returns from the screen. While this separation was satisfactorily accomplished, the coal product ran considerably higher in ash than the original coal. As to the value of its reducing properties, the writer is not prepared to say. There is no doubt, however, that the plants in the United States will investigate this question further in the future.

General Operation

The residue was fed by hand into the crusher (through which a small stream of water flowed) and elevated to the revolving screen. The undersize was spouted to the Hancock jig and the oversize to the rolls. As previously stated, there was no automatic feed, and it was therefore difficult to keep the screens properly bedded at all times. Another difficulty encountered was the collecting of very small pieces of metallic zinc and iron upon the first screen bed, necessitating the frequent readjustment of the bedding over this particular screen. The cutting out of the oversize or taking it to the Harz jig for separation of coal simply transferred the trouble. The question, however, is not a serious one, provided careful work be performed on the furnaces.

Cost of Concentrating by Jigging

Based upon feeding 100 tons of crude residue to the Hancock jig per 24 hours.:

	Old Residue	New Residue
Two engineers	$5.00	$5.00
Two hutch men	4.00	4.00
Four feeders	8.00	8.00
One helper	1.80	1.80
Teaming	6.00	...
One blaster	1.75	...
One helper	1.50	1.50
Labor on pond	1.50	1.50
Water	2.00	2.00
Blasting materials	1.13	...
Repairs	1.68	1.68
	$34.66	$23.98
Cost per ton crude	0.35	0.24
Cost per ton conc.	1.05	0.72

Test Run No. 1

Fresh Charge Residue—Time 8½ Hrs

	Percentage				Oz. Per Ton						Screens	
	SiO_2	Fe	Mn	Zn	S	Pb	Ag.	F.C.	V.M.	Mesh	Wire

Returns	16.2	....	....	....	....	56.5	1.1	42.4
Orig. Coal	10.3	2.2	....	....	....	66.6	7.5	25.9
Recovery	...	45.5	....	52.8	41.5	....	....	....

Weights and Values

	Wt.	Value Per Ton	Cost Per Ton	Net Per Ton	Total Realization
Through 5-Mesh	56,600	$5.73	$5.70	$0.03	$0.85
Hutch 1	6,840				
Hutch 2	2,440				
Hutch 3	3,372				
	12,652	13.77	5.66	8.11	51.33
Coal	14,000 (approximately)				

There is a decided advantage in concentrating, which is mainly due to the increase in the per cent of lead, which increases its value per unit, and a lower treatment charge.

TEST RUN NO. 6

Blue Powder Residue from Very Fine Leady Ore, Hancock Jig

	SiO_2	Fe	Zn	Pb	Ag	Screens Mesh	Screens Wire
Crude residue	10.1	12.7	5.8	8.7	6.3	....	....
Hutch 1	7.3	26.8	11.8	28.6	18.0	6	16
Hutch 2	10.8	27.8	11.0	19.2	14.6	7	18
Hutch 3	18.1	32.5	9.0	13.1	10.6	7	18
Hutch 4	21.0	14.2	5.8	8.0	6.5	....	....
Slimes	....	....	....	7.1	....	....	....
Recovery	....	37.3	33.8	44.3	43.0	....	....

Weights and Values

	Wt.	Value Per Ton	Cost Per Ton	Net Per Ton	Total Realization
Crude	46,160	$6.60	$5.70	$0.90	$20.79
Hutch 1	3,290				
Hutch 2	2,585				
Hutch 3	2,600				
Hutch total	8,475	17.37	4.73	12.64	53.47

A total difference in favor of concentrating of $32.68, or $1.41 per ton of crude, although the recovery is low.

This class of material could not be concentrated by dry screening, owing to its sintered nature.

The general conclusions drawn by the writer from the preceding tests are: First, that when the crude charge residue shows an appreciable net value it will not pay to concentrate by the Hancock jig; second, that the blue-powder residue seems to concentrate better, and may pay to jig, whether it shows a net value or not in the crude; third, that the fresh residue concentrates much more satisfactorily than the old or weathered residue.

With respect to the last test, Hutch No. 4 probably could be further concentrated by means of tables, vanners, or otherwise. While it would not be considered good practice to retreat Hutch No. 4 over the jig, the following test indicates that the jig may be overloaded, and that an automatic feed to same might improve the results.

HUTCH 4 REJIGGED

	Wt.	SiO_2	Fe	Zn	Pb	Ag
Crude	12,800	17.8	21.5	5.5	3.0	6.8
Hutch No. 1	720	11.4	31.5	10.5	6.7	10.5
Hutch No. 2	400	10.8	32.5	9.6	5.3	11.0
Hutch No. 3	440	12.0	29.5	8.8	4.0	9.3
	1,560					

This recovery looks very good, but owing to the incompleteness of the test no definite conclusions can be drawn. In fact, all of the tests made upon Hutch No. 4 material merely indicate the difficulty of further concentrating same.

Burning Residues

A certain degree of concentration may be obtained by burning the carbonaceous material contained in the residue, or at least the greater proportion of it. There are two special advantages gained by this method aside from the concentration, namely: the removal of the carbonaceous material, which is a detriment in smelting, and the sintered form of the product, which enhances its smelting value due to its mechanical condition and reduced dust loss in smelting. One of the zinc plants has had this method in practical use for some time. The residues are simply piled out upon the ground, over pipes or channels through which a blast of air is forced after the ignition has been started, the burning process being kept up until the greater part of the carbonaceous material has been consumed. The

blast is then turned off and the pile allowed to cool, after which it is broken up, loaded into cars, and shipped. The advantages of the process undoubtedly overbalance any metal losses.

Smelting Residues

A great many tons of residue containing precious metals have been smelted during the past 12 years at the various lead smelters, using a small proportion of residue mixed in with the general charge. Only one attempt, however, has been made in this country to smelt the residues as the principal burden of the charge. This experiment was made about 1903, at one of the zinc company's plants.

As there is a difference of opinion regarding the best method of treating the residues, the writer herewith gives his personal notes upon the above mentioned experiment, and a deduction of what might possibly be done under more favorable circumstances, with a view of arriving at a comparison between smelting and other processes of concentration.

Notes from Smelting Experiments

The furnace was only 36 in. by 90 in. at the crucible and 14 ft. from center of tuyeres to feed floor. The furnace being small, and a high per cent of zinc on the charge, it had to be let out frequently to bar off the accretions, the longest run being about six weeks.

Average Record of Furnace Operations for the Above Seven Months

Oz. Blast	Tons Per Fur. Day	% of Pb. on Chg.*	% of Coke	% Matter Produced	—% Saving— Ag	Au	Pb
19.0	45.6	9.1	13.0	7.2	90.8	92.4	92.0

While the office record showed a loss of about $2,000 per month, it was due not so much to the metallurgical failure to smelt the residues as it was to the small size of the furnace and the high percentage of zinc left in the residues at that time; also to the high minus margin on the Missouri galena, due to the conditions under which it was bought.

The period of the experiment was 273 days, while the actual furnace days were only 149. The results are, therefore, no criterion of what may be accomplished under more favorable conditions.

To anticipate what may be accomplished under more favorable conditions, and reduce the above results to

Results Actually Obtained Basis Upon 149 Furnace Days

	Per Day	Per Fur. Day
Labor and overhead expenses	$71.00	$117.20
Sampling and assaying	2.30	4.15
Supplies	2.00	3.72
Repairs and renewals	4.90	9.00
	$80.20	$134.10

	Tons Per Day	Minus Margin	
Galena	2.8 ×	— 6.05 =	— 16.94
Lime rock	6.5 ×	— 1.09 =	— 7.09
Iron ore	6.7 ×	— 4.25 =	— 28.48
Coke	6.1 ×	— 8.20 =	— 50.02
	— 22.1		— 102.53
			— $236.63

		Plus Margin	
Residue	13.3 ×	+ 9.34 =	124.22
Ores	12.2 ×	+ 3.76 =	44.87
	25.5		+ 169.09
Loss per day			— $67.54
Loss per month			$2,026.20
Loss per ton of residue			— $5.07

a fairer comparison with other methods of treating the residue, it is not unreasonable to assume the following:

1—Per cent of zinc in the residue, 7 instead of 14.

2—Due to this, a slag lower in iron could be run, thereby replacing some of the Missouri iron ore with residue.

3—Larger furnace, treating 100 tons per day, at a less cost per ton.

4—Furnace down only 28 days out of the 273.

Results Upon Assumed Basis

	50 Tons Per Day	100 Tons Per Day	Per Fur. Day
Labor and overhead expenses	$71.00	$83.50	$89.40
Sampling and assaying exp.	2.30	4.60	4.95
Supplies expenses	2.00	4.00	4.28
Repairs and renewals expenses	4.90	5.80	6.21
	$80.20	$97.90	— $104.84

	Tons Per Day	Minus Margin	
Galena	5.6 ×	— 6.05 =	— $33.88
Lime rock	14.0 ×	— 1.09 =	— 15.26
Iron ore	9.0 ×	— 4.25 =	— 38.25
Coke	12.2 ×	— 8.20 =	— 100.04
			— 187.43
			— $292.27

		Plus Margin	
Residue	30.00 ×	+ 9.34 =	+ $280.20
Ores	24.4 ×	+ 3.76 =	+ 91.74
			+ $371.94
Profit per day			+ $79.67
Profit per ton of residue			+ 2.66

The comparison between smelting and shipping the residue direct would be as follows:

	Total Margin Per Ton of Residue	Cost Per Ton of Residue	Net Per Ton of Residue
Smelting	$12.40	$9.74	$2.66
Shipping	8.10	5.70	2.40

If the residue was dry screened it would show a better profit than above. It is therefore very doubtful if it will pay to smelt the residues, except under the most favorable circumstances, or when they do not constitute the bulk of the charge.

The above comparison is based upon a residue of the following analysis and valuation:

Analysis

SiO_2, 10.5%; Fe, 32.7%; Pb, 2.3%; Ag, 10 oz., and Au .03 oz. per ton.

The Filter-Press

By D. R. Sperry

PERHAPS no machine employed in the chemical industry at the present day is so little understood and at the same time so widely used as the filter-press. Beyond a doubt this is due largely to the great variety of ways in which the machine is used. Persons who are in intimate contact with filter-presses as used in their particular branch of the chemical industry are informed regarding them only as arranged and used in their process. They know very little of the hundred and one other arrangements in which the filter-press can be used and is used in other chemical processes. General knowledge of the filter-press, therefore, is not likely to be found among the actual users of the apparatus. The lack of general information regarding it in text-books and in technical publications, due probably to the reasons given above, produces a lack of information on the subject among those who are not already users. It is quite probable that there are a great many instances in chemical processes wherein the filter-press could be used to advantage were it possible for engineers and chemists to obtain a broad general understanding of the device. It is the writer's purpose to convey by means of this article a general knowledge of the filter-press, and it is his earnest hope that it may prove an efficient tool for engineers and chemists in solving their problems.

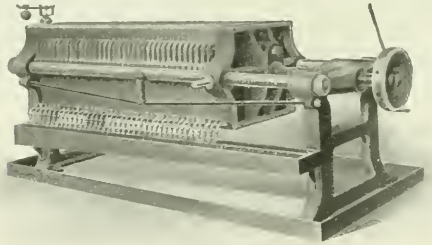

FIG. 1. FILTER-PRESS

Field of the Filter-Press

The field of the filter-press is very broad, which explains its great versatility, inasmuch as it may be used wherever the great principle of the separation of solids from liquids is employed. There are very few cases indeed in the various branches of the chemical industry where it is not necessary in some way to separate solids from liquids. In most of these lines, not all, to be sure, the filter-press may be used. Its field extends also to a certain extent into that of lixiviation and extraction, as will be explained later.

What the Filter-Press Does

The filter-press does two important things, namely:

(a) Separates solids from liquids.

(b) Washes, lixiviates or extracts.

The first is performed by forcing or pumping the liquid containing the solids through a filter-base, usually cotton duck, thus retaining the solids in the cells or chambers of the filter-press. The liquid flows away, usually through cocks placed on each cell. The second process, called washing, consists in forcing water or some other liquid into the filter-press in such a way that it flows through the deposited solids, displacing therefrom the liquid contained in the pores which may later be recovered from the wash. Sometimes the wash water dissolves some desirable substance in the cake or solids, permitting its recovery later.

The filter-press can also cause thorough precipitation of a substance contained in the liquid by reason of the intimate contact which the liquid necessarily makes with the solids, causing the precipitation, as it passes through the cake.

The filter-press may separate solids from liquids, maintaining the process at some desired temperature. Thus a substance can be chilled and crystals filtered out, or a substance crystallizing at ordinary temperatures can be filtered hot in order to remove impurities and not crystals.

Commercial Uses of the Filter-Press

Some of the commercial uses of the filter-press are the following:

(a) Making dull liquids clear and sparkling for appearance sake only, as in cider, near-beers, liquid soaps, etc.

(b) Removing substances from liquids for re-use or which would injure the product if allowed to remain, as in removing Fuller's earth or bleach from lard,

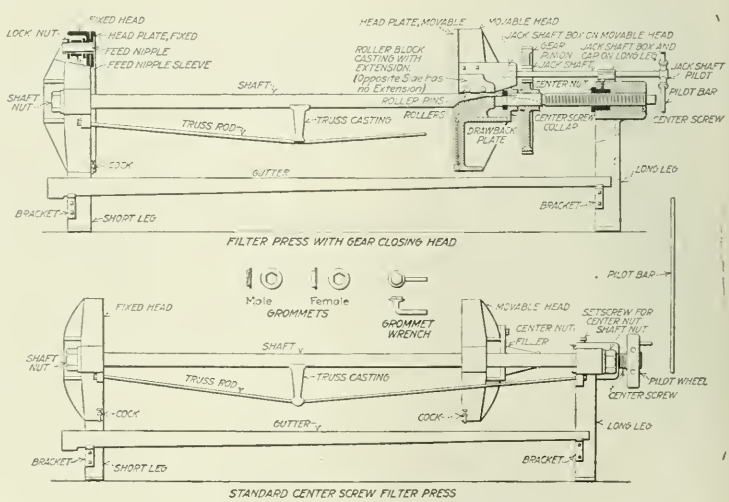

FIG. 2. NAMES OF PARTS OF A FILTER-PRESS

nickel from hydrolized vegetable oils, lime from sugar juices, etc.

(c) To separate a valuable liquid from a mass and then dissolve out or lixiviate some valuable substance contained in the solids, as in the treatment of cyanide slime in gold metallurgy.

(d) To separate a valuable mass from a liquid and then to lixiviate the valuable portion of the mass, the liquid being used solely as a conveyor for the mass, as lixiviating ground quartz in gold metallurgy after it has been deposited in the press by means of water.

(e) To reduce a muddy mass to a more convenient form, as in sewage sludge, china clay, etc.

(f) To save fuel in evaporation by removing the greater part of the moisture in the filter-press, as in the manufacture of lithopone, white lead, etc.

(g) To aid precipitation by mixing a substance causing precipitation with the liquid and pumping the mixture in a filter-press, as in gold metallurgy where zinc-dust is added to cyanide solution and is fed into a filter-press, the intimate contact of the cyanide solution causing gold to precipitate as it flows through the cake of zinc-dust.

(h) To crystallize out a substance which at ordinary temperature is liquid, by filtering in a refrigerated filter-press at which temperature crystals form, as in filtering certain oils.

(i) To clarify a substance which at ordinary temperature is crystalline, by filtering in a steam-jacketed filter-press at a temperature too high for crystals to form, as in Glauber's salts, where hydroxide of iron is removed.

(j) To separate a solid from an unstable liquid in a closed-discharge filter-press where the liquid does not come in contact with the atmosphere, as in certain varnishes and in cases where the liquid evaporates easily, as alcohol.

Advantages of the Filter-Press Over Other Forms of Filters

The advantages of the filter-press over other forms of filter are as follows:

(a) Includes the greatest amount of filter area per unit of floor space.

(b) Cost of filter area per square foot the lowest.

(c) Lowest cost of maintenance and repairs.

(d) Lowest operating expense due to the fact that common labor can operate a filter-press.

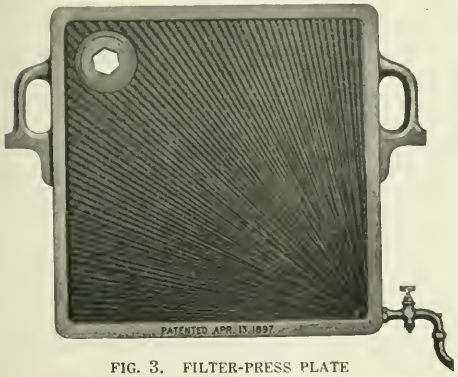

FIG. 3. FILTER-PRESS PLATE

At this point it is well to show what a filter-press looks like, and for that purpose there is shown in Fig. 1 a much used type. Cursory examination shows that it is a machine consisting of two general parts, namely, a screw-press supported on legs and a number of plates resting on the bars of the press and held together between the heads. Minor attachments consist of a row of cocks and a gutter. This machine is a filter-press in one of its most simple forms.

Definition of a Filter-Press and a Popular Misconception

A filter-press is a press which is employed to hold together the component parts of a filter.

A popular misconception of the name "filter-press" is that it is a machine which both filters the solids out of a mixture and squeezes or presses the solids as well. Many also imagine that a filter-press is some kind of a

FIG. 4. FILTER-PRESS GROMMETS

hydraulic press after the order of oil presses which squeeze the oil from seeds. The definition given above tells us that the filter-press is a press which presses a filter, just as a letter-press is a press that presses letters, or a hay-press is a press that presses hay. It should be remembered that while a filter-press presses a filter, it does so only to hold the filter together and not to press the solids within the filter.

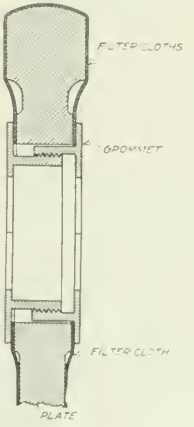

FIG. 5. SECTION THROUGH PORTION OF FILTER-PRESS PLATE SHOWING POSITION OF GROMMET WITH FILTER CLOTH IN PLACE

Names of Parts of the Filter-Press

In Fig. 2 are shown the names of parts of a filter-press both with and without gears for closing. It is quite interesting to note the great variety of names which users of filter-presses have given to the various parts. This is to be expected, of course, as up to the present time there has been no way of properly determining the correct names of parts. For example, the small parts called grommets, used to hold the canvas to the plates, have been called lock-nuts, cloth holders, flanges, ferrules, clamps, etc. Such a multiplicity of terms leads to confusion, and, therefore, in this article the names of parts given in Fig. 2 will be used exclusively.

Filtration Without Frames

The simplest form of filtration in a filter-press is that in which recessed plates are used. In Fig. 3 is shown a recessed plate with grommet screwed in place. To use these plates, they are first "clothed"; that is, a piece of the filter-base, usually cotton duck, is cut long enough to lay over the top of the plate and cover both sides. A hole is cut in the cloth on each side of the plate where it covers the grommet hole, and the grommet is applied. In Fig. 4 is shown the grommet hole

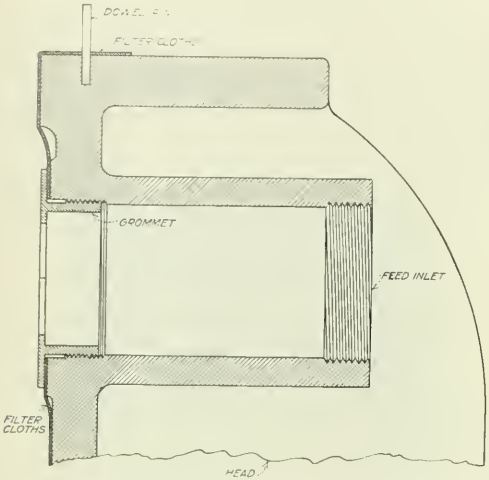

FIG. 6. SECTION THROUGH PORTION OF FIXED FILTER-PRESS HEAD SHOWING HALF-GROMMET AND FILTER CLOTH IN PLACE

in a plate (left-hand side), three grommets, one of which is unscrewed (left center of picture) and a grommet in place with cloth properly applied to plate (right side of picture). The grommet when thus screwed in place holds the cloth tightly down against the finished portion of the plate surrounding the grommet hole. A cross-section through the grommet hole when thus in place is shown in Fig. 5. The surface of both of the heads of the filter-press is similar to that shown on the plate in Fig. 3, except that on the movable head there is no grommet hole. A cloth is thrown over the surface of each head and a hole cut only in the cloth on the fixed head where it covers the grommet hole. A half-grommet, usually the male part, is screwed into the grommet hole of the fixed head, thus holding the cloth to the finished surface, surrounding the same in a manner similar to that done in the plates. A cross-section of a portion of the fixed head through the half-grommet is shown in Fig. 6. There are usually provided two dowel pins on the top of the heads, by means of which the cloth can be kept from falling down. This can be noted in Fig. 6.

When all the plates and heads are thus clothed, the plates are placed within the filter-press. A cross-section through the filter-press and plates when this is done is shown in Fig. 7. A study of this cross-section will disclose the fact that when the plates and heads are clothed as described there is formed throughout the length of the press a number of cells or chambers between each plate and between the heads and the adjacent plates. It will further be observed that all of the cells thus formed are connected together in multiple by means of the openings through the grommets. In fact, the grommets form a continuous channel running from head to head and joining together all of the chambers formed by the recessed surfaces of plates and heads. If now the screw of the filter-press is tightened so as to strongly compress the plates and heads together, the cloth covering the finished border of the plates and heads acts at that point as a packing, making the cells nearly watertight. It is interesting to note that there are two thicknesses of cloth at the joints, making a very thorough packing. Suppose now that a mixture of solids and liquid is introduced at the inlet of the fixed head. The result will be that the mixture will run the whole length of the press along the channel formed by the grommets filling all of the chambers or cells. If the mixture is placed under pressure there is but one thing which can happen, namely, the liquid of the mixture will flow through the cloth which bounds the chambers, while the solids will be left and may ultimately completely fill the chambers. The liquid, as it emerges from the back side of the cloth, comes into contact with the surface of the plate and is conducted by means of grooves, see Fig. 3, to one of the corners, where it

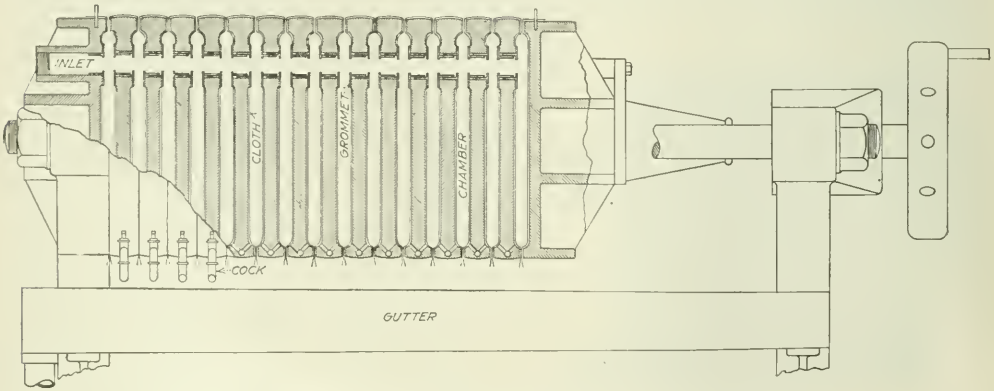

FIG. 7. CROSS-SECTION THROUGH FILTER-PRESS FITTED WITH RECESSED PLATES

flows into a small hole that leads to a cock placed on the corner of the plate. From the cock it empties into a gutter, from whence it is piped to a suitable receptacle. When the chambers become filled with solids or when the flow of liquid has become very small, the pressure is removed from the entering mixture and the screw of the filter-press is loosened so that the plates may be separated from one another. This is accomplished by pushing back the slide head as far as it will go and then pulling back each plate one by one, removing the solids as each one is brought forward. When the solids have thus been removed the plate which was last drawn up is slid back to the fixed head, the workmen seeing that the last traces of solids are removed from the cloth packing surfaces. Similarly, each plate is successively drawn back and inspected, until the movable head is reached, when it too is drawn back into place. Pressure is then applied to the screw and the filter-press is ready to receive another lot of the mixture. In the hands of the laborers who are accustomed to the work the process of removing the solids is not so long a process as one might suppose. The writer knows of a case where filter-presses containing forty plates have been opened, the solids removed, and closed again in an average time of fifteen minutes. Two common laborers perform the operation with ease.

NOMENCLATURE

Now that the simplest form of filtration in a filter-press has been described, it is well at this time to give the technical terms applied to the various steps in the operation as follows:

Clothing the Press.—Putting cloths on the filter-plates.

Closing the Press.—Squeezing the clothed plates together in the filter-press.

Filling the Press.—Pumping or otherwise forcing the mixture to be filtered into the filter-press.

Opening the Press.—Relieving the pressure on the screw of the filter-press and spreading the plates apart, at the same time removing the solids.

A Complete Cycle is the term applied to the successive operations of closing, filling and opening.

Cake means the solids deposited within the filter-press.

Filtrate.—The liquid issuing from the filter-press.

Batavia, Ill.

New York Section Société Chimie Industrielle

The organization meeting of the New York Section of the French Society of Chemical Industry was held at the Chemists' Club, New York, Friday evening, Jan. 18. As a result of a previous mail inquiry, about 150 chemists signified their intention of joining the new section.

The following officers were elected: L. H. Baekeland, chairman; Jerome Alexander, vice chairman; George F. Kunz, treasurer; C. A. Doremus, secretary. The council comprises Charles Baskerville, Henri Blum, M. T. Bogert, C. F. Chandler, Ellwood Hendrick, W. H. Nichols, R. E. Orfila, G. E. Valabrigue, E. P. V. Verge and Henri Viteaux. Following the election of officers a formal meeting was held, at which provision was made for election of the charter members. Dues were set at $7 per annum, and the date of the first meeting was announced as Feb. 15 in Rumford Hall, Chemists' Club.

M. René Engel, secretary of the parent society in France, was present and announced that the society would begin in February to publish its new journal, *Chimie et Industrie.*

Ordnance Department Needs Civilian Workers

The Ordnance Department of the Army urgently needs several thousand civilian workers, as specified in the following lists:

7700 clerical positions, including stenographers, typewriters, production clerks, statisticians, etc. Positions pay from $1,000 to $1,800 per year.

TESTING POSITIONS

200 engineers of tests of ordnance material, $1,500 to $2,400 a year.
200 assistant engineers of tests of ordnance material, $1,000 to $1,500 a year.

MECHANICAL TRADES POSITIONS

2500 machinists, $4.00 a day.
500 machine operators, $2.75 a day.
200 drop forgers, $5.75 a day (piecework).
300 tool makers, $4.50 a day.
Large numbers in practically all other trades.

DRAFTING POSITIONS

500 mechanical draftsmen, $800 to $1,800 a year.
50 gauge designers, $2,000 to $3,000 a year.
100 apprentice draftsmen, $480 a year.

INSPECTION POSITIONS

300 inspectors of small-arms ammunition, $1,500 to $2,400 a year.
100 inspectors of artillery ammunition (high-explosive shell loading), $1,500 to $2,400 a year.
100 inspectors of artillery ammunition (forgings), $1,500 to $2,400 a year.
100 inspectors of artillery ammunition (ballistics), $1,500 to $2,400 a year.
300 inspectors of field artillery ammunition steel, $1,500 to $2,400 a year.
300 assistant inspectors of field artillery ammunition steel, $3.50 to $5.00 a day.
500 inspectors of small arms, $1,500 to $2,400 a year.
100 inspectors of material for small arms, $1,000 to $1,800 a year.
100 assistant inspectors of cannon forgings, $1,500 to $2,400 a year.
100 assistant inspectors of finished machine parts, $1,500 to $2,400 a year.
100 assistant inspectors of gunfire control instruments, $1,200 to $1,500 a year.
50 assistant inspectors of steel helmets, $1,000 to $1,800 a year.
50 assistant inspectors of cleaning and preserving materials, $1,000 to $1,800 a year.
400 inspectors and assistant inspectors of powder and explosives, $1,400 to $2,400 a year.

For further information apply to the representative of the United States Civil Service Commission at the post office or custom house in any city, or to the Civil Service Commission in Washington, D. C. Except for the positions of stenographer and typewriter, typewriter operator, multigraph operator, and general clerk, applicants are not assembled for a written examination, but are rated principally upon their education, training and experience, as shown by their applications and corroborative evidence. The positions are for men only, except in the clerical work, where women are also accepted.

Intensive Toluol Production—I

Proposed Improvements in the Absorbing and Stripping Process

By FRANK E. LICHTENTHAELER

IT may be safely stated that a sufficient supply of toluol will prove a prime factor in determining our success in the war. However manifest this may be, the plain fact that the supply is inadequate, and the immediate need of meeting the situation aggressively and in a well-directed manner, do not appear to be comprehended to the full extent demanded by the exigency. This does not fail to take account of existing plans for increasing the supply, but refers more directly to an observed tendency to think in terms of the present only; and if one may judge from information published to date, the main issue, an unfailing supply of toluol, is hopelessly obscured by repeated descriptions of some particular process and incidental apparatus without evidence of a clear understanding of basic principles involved, yet with an air of finality that does not seem warranted on any sound engineering ground. Unessential details have been painfully emphasized to the exclusion of the broad underlying facts that, after all, will determine the eventual degree of success. A comprehensive plan of procedure founded on a scientific analysis of the situation seems to be lacking.

War Requirements

It has been stated that 22,000,000 gallons of toluol must be forthcoming by September, 1918, to supply an army of one million men. It is conceded that ultimately we may have four or five million men in the field and presumably the toluol production must increase proportionately. Published figures seem to account for approximately 12,000,000 gallons in addition to the present output from coke ovens, most of the latter already being taken by the navy. Yet the strongest accompanying statement is that "it is interesting to note that this is more than half the amount required." The significant point escapes emphasis: Where, definitely, is the other half?

Our Government is developing a wonderful machine for the creation of a vast trained army, the all-sufficient power of which will insure victory and a real peace. An equally efficient machine must be developed simultaneously to supply the endless quantities of munitions and materials from which they are made, and at a rate far in excess of the army's immediate needs. This is the greatest task for those of us who stay behind, and if we fail we have betrayed our brave men who are going with complete confidence that we will do our part as they do theirs.

The undoubted urgency of these matters would seem to warrant a broad survey of the situation in the hope of arriving at some elastic plan of procedure capable of extension to meet demands far beyond to-day's limited vision. At a time of great stress it is inadvisable to attempt a nice calculation of quantities of essential supplies that are likely to be needed. Sound judgment warrants the assumption that ultimately we may have to provide ourselves and our Allies to an extent far exceeding all possible forecasts. Our plans, therefore, must contemplate a large excess of all essential materials. An overproduction will be forgiven as mere insurance, protecting present and future generations. A shortage will doom us to almost certain defeat and the shame of having failed those who go to bear the brunt of battle.

The purposes, then, of this article are threefold:

First: To warn against delay in providing an unlimited supply of toluol. All available resources, great and small, should be developed simultaneously, not gradually in order of their importance only as the need becomes more pressing. The estimated deficiency must come from new and undeveloped sources, such, for instance, as the cracking of petroleum in excess of the normal requirement for carburetting purposes; and there must be a liberal reserve anticipating the invariable error of underrating ultimate needs.

Second: To advocate more simple and economical methods of toluol production, that our financial and material resources may be conserved to the utmost. Specific recommendations along this line constitute the main subject matter of this article.

Third: To emphasize the costly mistake of our Allies, if we may judge from observations in Canada, in respect to wholesale waste of toluol in the process of munitions manufacture. If we can but bring ourselves to foresee the likelihood of a similar condition in our own munitions factories, much could be done in the way of remedying or preventing needless loss of this essential material and the incidental cost and labor attending its production.

Development of Resources

With this attempt to state the fundamental proposition and with a strong desire to contribute toward a more rational means of meeting its terms, we proceed directly to suggest specific recommendations in respect to improved methods of toluol production. Reviewing briefly the question of supply, there are three main sources usually referred to:

1. Coke-oven gases.
2. Illuminating gases.
3. Cracked petroleum products.

In respect to the first source, the utmost pressure should be brought to bear in the matter of new by-product coke-oven installations, including equipment for treating the gas and tar for maximum yield of toluol and benzol. These installations require considerable time, and the comparatively few available companies, experienced primarily in the intricacies of by-product oven construction, should have their efforts directed and concentrated on a rapid and unlimited development of this field. This alone constitutes a task, the accomplishment of which is of no less importance than the exten-

sive ship-building program of the United States Shipping Board. Certainly the experience and manufacturing capacity of these same concerns should be fully utilized in respect to recovery and refining apparatus required in connection with by-product oven installations. It should not be too quickly assumed, however, that their very creditable progress in respect to recovery methods and apparatus has reached the same high plane of development that applies to their work in connection with coke ovens. It stands to reason that other American concerns, who have made a life-work of solvent recovery and refining problems in the same sense that coke-oven manufacturers have specialized on coke-oven practice and with equivalent progress in the development of their knowledge and skill, may likewise have important contributions to offer pertaining to advance progress in recovery and refining methods not included in the usual scope of gas engineering and evidently unappreciated by specialists in coke-oven practice. We hope to show later that a very material improvement is possible along these lines—a highly desirable improvement if it helps to reduce the practice to one of greater simplicity and higher economy.

Turning next to the third source mentioned above, namely, cracked petroleum, we believe this will ultimately become of great importance. After all of the gas works have contributed their utmost, it will probably develop that the output alloted to by-product coke-oven plants cannot be increased with sufficient rapidity to span the gap, in which case it would appear necessary to turn to the cracking of petroleum, because considerable information is available on the subject and the necessary equipment could be provided within a comparatively short time. Certainly this possibility should be anticipated, and if the growing coke-oven supply cannot be depended upon except for remote needs, work should be started immediately along the lines of petroleum cracking, especially as this appears to be a source capable of unlimited development. In this connection it is desired to mention work done by the Standard Oil Company in producing benzol and toluol from California crude oils. It is our belief that developments in this quarter have passed beyond the experimental stage, making it possible perhaps to estimate a dependable future output. We have built apparatus for producing "toluol pure" from the crude light-oil mixtures resulting from cracking California oils, and sincerely believe that it is a field offering possibilities that cannot safely be overlooked.

Source two, above, namely illuminating gases, absorbs our main attention for the present, principally because it offers a large available supply that can be made to yield results most quickly. Besides it is realized that the carburetting of water-gas is essentially a petroleum cracking process, with the great advantage that hundreds of plants are available, requiring merely the addition of suitable recovery apparatus. This article deals mainly with the situation in respect to source two—the recovery of toluol from illuminating gases. We recommend a comprehensive and simultaneous recovery applying to carburetted water-gas, coal-gas and oil-gas, including their respective tars. The same procedure that we will suggest would apply also to sources one and three, above. This should be borne in mind in connection with a broad study of the entire situation with the purpose of simplifying and increasing the efficiency of recovery methods as applied to whatever source. That is to say, recommendations that may appear pertinent to illuminating-gas recovery methods might also be expected to improve the economy of recovery from oven gases and all other sources, as well.

The simultaneous working of all toluol-yielding sources, as suggested, raises the question of how to handle the many cases involving associated and inseparable paraffins in an excess of 2 per cent, which has been set as the limit above which the toluol is claimed to be unfit for explosive purposes. There stands against this claim, however, an equally authoritative statement to the effect that upward of 10 per cent inert paraffins does not interfere with subsequent nitration, at the same time suggesting the separation of the paraffins from the mono-nitro product by simple distillation. This latter claim may have been disproved, but we find no information to this effect. Is it not more likely to be a case of prejudice on the part of munitions manufacturers who have been long accustomed to insist on "toluol pure"? Now toluol containing 10 per cent of inert material is essentially "toluol pure," and it should be very definitely determined whether or not mere reluctance to add a simple and inexpensive distilling operation, coupled with characteristic bias in favor of antiquated methods, is the sole explanation and reason for casting aside a substantial amount of toluol that can ill be spared. The oft suggested plan to so carefully control the carburetting processes as to keep the paraffin production below 2 per cent would appear to be a far more difficult undertaking than minor modifications in the established practice of munitions manufacture.

The Absorbing and Stripping Process

It may not be amiss at this point to establish a reason for selecting the so-called "absorbing and stripping" process to the exclusion of other methods. We recommend this procedure notwithstanding the fact that we hold basic patents covering solvent recovery from gas mixtures by means of combined compression and refrigeration. This latter process is practically and extensively employed in connection with the recovery of gasoline from casing-head gas, and we might be supposed to have a prejudice in its favor. The "absorbing and stripping" process, however, lends itself in every way to existing conditions at gas plants throughout the country, and the same applies to by-product coke-oven installations and the few existing petroleum-cracking plants. The compression and refrigeration process, unfortunately, requires the use of very large and expensive compressors and expanding engines, and the procedure involved is so radically different, more difficult and dangerous than comes within the experience of the industries to be dealt with that every conceivable argument for employing this process appears to be disproved. So far as we know, there are no other practical methods that might be employed, so we are certainly justified in concentrating efforts on a general betterment of the so-called "absorbing and stripping" process.

We propose to treat this subject under four main headings, namely: Absorbing, Stripping, Concentrating and Refining. Part one of this article refers more particularly to improvements in absorbing and stripping, leaving discussion of the remaining two sub-divisions to be covered by part two to follow. This division of the

subject is suggested by the fact that all gas works will be interested in absorbing and stripping, but whether or not they will engage in concentrating and refining of the light oil is an important point in question which also we will leave for later discussion.

Lummus Absorption System

We have endeavored to conceive an ideal procedure and accompanying apparatus to fit existing conditions in both large and small plants, insuring maximum economy of production and least demand on the facilities, skill and financial resources of the gas manufacturer. In fact, this same problem under slightly different aspect was presented to us as far back as July, 1913, in connection with the recovery of wood alcohol from its vaporous mixture with the fixed gases of charcoal by-product ovens. We devised a method at that time which formed a nucleus for our subsequent development of the so-called Lummus system of recovering the condensable constituents of vapor-gas mixtures. The original conception was not put into practice because it represented a departure from usual methods employed at wood chemical plants and we were unable to overcome the prejudice in favor of long-established practice, although wasteful and illogical. However, more recent developments in connection with petroleum cracking gave us the much hoped for opportunity to crystallize our ideas on this subject and definitely design and build plants on a commercial scale.

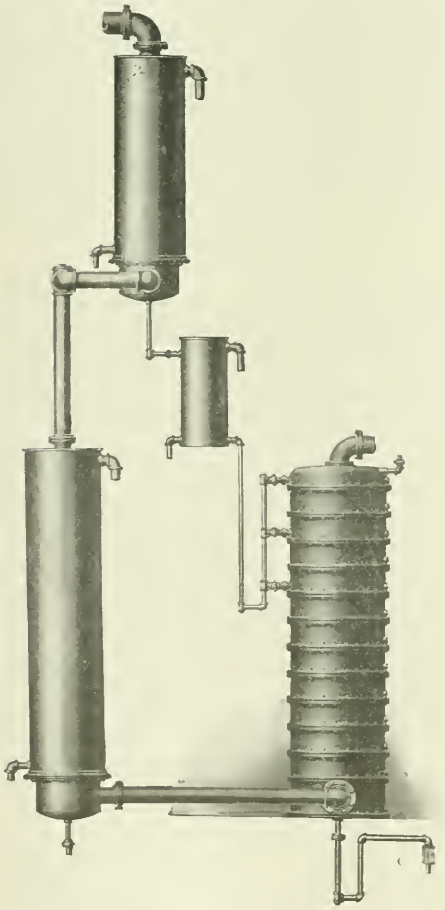

FIG. 1—ABSORPTION SYSTEM OF SOLVENT RECOVERY FROM FIXED GASES

Accompanying Fig. 1 illustrates the general arrangement of apparatus as employed in connection with the Lummus absorption system of solvent recovery from fixed gases (patent pending). Briefly, the method consists in scrubbing a residual gas-vapor mixture by means of a high-boiling condensate that has been previously removed from the initial gas-vapor mixture. The operation is described as follows:

The initial gas-vapor mixture, whether it be coke-oven gas, illuminating gas or the products of cracked petroleum, is led into a condenser, shown at the top of Fig. 1, in which partial condensation is effected, limited principally to the higher boiling constituents. This condensate is cooled in the cooler, shown directly below the primary condenser, and then admitted to the top of the absorber or scrubber, shown at right. The residual gas-vapor mixture, issuing from the primary condenser, is thoroughly cooled in the large cooler shown at left, from which it passes into the base of the scrubber, within which it is caused to bubble repeatedly and in counter-current fashion through seals flooded from above with the cold high-boiling condensate, as previously described. It is at once obvious that the scrubbing or absorbing operation is in all essential respects the same as that commonly employed in all absorbing operations. We strongly recommend a type of absorber that insures positive counter-current contact between gas and absorbent, instead of the "hurdle" type of absorber, which permits of surface action only, thereby requiring an excessive amount of absorbent and an absurdly large superficial area. However, this important distinction will be discussed later in greater detail, the main point to be emphasized here being the novel feature of the system described, whch consists in the use of the higher-boiling constituents of the initial gas-vapor mixture as the ideal absorbing medium. It directly follows that the use of this available absorbing medium removes the need of an external petroleum or tar-oil absorbent, and incidentally eliminates the many troublesome and inherent difficulties common to the repeated use of such absorbents.

Tar as Ideal Absorbing Medium

It will be immediately realized that the gas-vapor-tar combination, common to all methods of illuminating-gas manufacture as well as to by-product coke-ovens and petroleum-cracking processes, directly lends itself to the same method of gas treatment described above. In the case of the gas works, the partly purified gas from which toluol is to be recovered has already been largely relieved of its burden of tar, the latter constituting the high-boiling portion of the initial gas-vapor mixture. This tar is none the less available as the ideal scrubbing medium for the residual, toluol-bearing, gas-vapor mixture, and it may be so used with many obvious advantages if certain simple conditions be complied with. Furthermore, the use of tar as the scrubbing medium has long since been removed from the

realm of mere theory and experimentation. The so-called Carpenter process, as successfully employed throughout Great Britain, according to best obtainable information, refers to the identical procedure that we here recommend and which, as stated, we have been using successfully in connection with the products of cracked petroleum and originally conceived by us in the summer of 1913. We therefore feel that we are not offering an untried process, and trust that the many advantages of this method of procedure will at least claim the attention and careful investigation of our Government officials who have in hand this important problem of intensive toluol production.

Accompanying Fig. 2 illustrates diagrammatically our proposed absorbing and stripping system, using tar originally contained in the gas as the ideal absorbing medium to remove toluol from the residual gas mixture.

The various steps involved in the operation consist in warming and dehydrating the tar, cooling the tar to 60 deg. Fahr. or lower, and then causing positive counter-current contact between the cold tar and the cold gas in a suitable absorber. The "benzolized" tar issuing from the absorber is finally treated in a continuous stripping still, in order to remove the total light-oil fraction comprising the portion recovered from the gas and also that originally present in the tar as well.

Condensers and heat interchangers are employed, as indicated, to improve economy in respect to heat consumption. The residual tar, free of its light-oil content, emerges from the process and is available for use as road binder or for other purposes as special conditions may determine.

Distinctive Features of the Lummus System

The following distinctive features of the above process should be especially noted: In the first place, tar which is already available at all plants constitutes the scrubbing medium, and thus obviates the necessity of employing a foreign absorbing oil. In the second place, the tar absorbent makes but one passage through the system. The repeated use of the absorbing medium, common to other processes recently suggested, is thus avoided, as well as the constant re-standardization of the absorbing medium and repeated treatments for removal of naphthalene, which in the case of the cyclic system otherwise soon renders the oil unfit for absorbing purposes.

Centrifugal Tar Dehydration

Careful dehydration of the tar is essential to insure high absorptive efficiency. In our opinion the dehydrating operation can be performed most economically by means of the centrifuge. It appears that even water-gas tar may be dehydrated in this manner if heated to approximately 80 deg. C. in order to obtain a favorable difference in gravity between the water and tar. Lunge describes this method of tar dehydration and mentions an observed cost in the neighborhood of 25 cents per ton. We have confirmed Lunge's assuring statements in respect to centrifugal dehydration and incidental cost of operation by discussions with American centrifuge manufacturers, and find that at least three reputable American concerns are familiar with the problem and are ready to build the special form of centrifuge required. One concern was prepared to state the cost of centrifugal dehydration of coal tar, calculated from test runs, at 44 cents per ton, based on a tar emulsion containing as high as 50 per cent of water. We had previously corrected Lunge's figure to 50 cents a ton, allowing for present abnormal cost of power and labor. In this connection it is interesting to note that two of the concerns referred to have experimental departments, suggesting the desirable possibility of submitting to them samples of tar as produced by

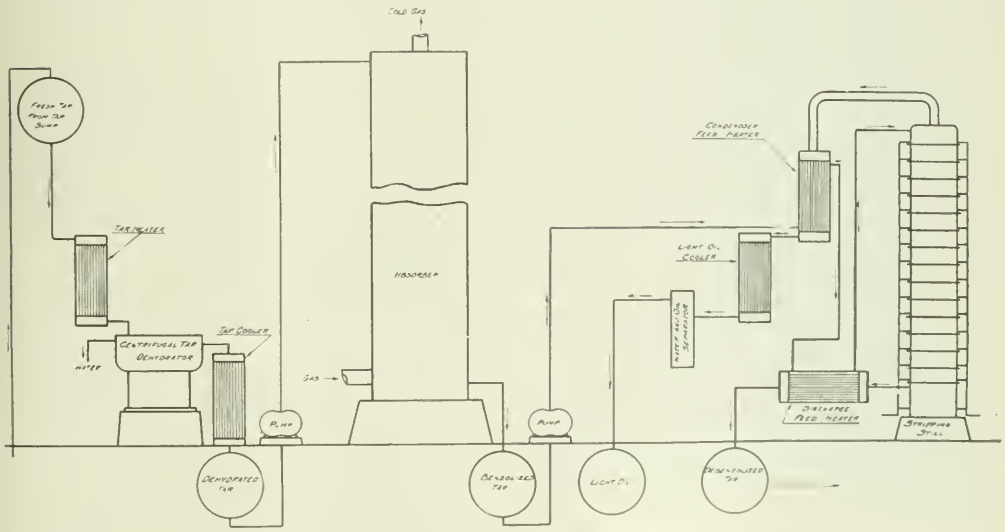

FIG. 2. ABSORBING AND STRIPPING SYSTEM

different gas works, in order that the best conditions for centrifugal dehydration could be determined for each particular case.

The "Cap-and-Seal" Absorber

In respect to absorbing apparatus, we strongly recommend the so-called "bubble" or "cap-and-seal" type. Accompanying Fig. 3 illustrates one arrangement of this type of absorber successfully employed by us for years past in connection with various solvent-recovery undertakings. The main arguments in favor of this type, as opposed to the "hurdle" type of absorber, are:

(1) The definite relation made possible between the quantity of absorbing medium used and the volume of gas to be scrubbed.

(2) The positive and repeated contacts assured between gas and absorbing medium.

This is to say, the "cap-and-seal" arrangement permits of admitting the exact amount of absorbing medium required to remove satisfactorily the volatile constituents of the gas in a single passage through the apparatus, which, together with the intimate contact caused between gas and absorbing medium, insures the utmost economy of operation. In the case of the "hurdle" tower, absorption is entirely dependent on surface contact, the ineffectiveness of which is clearly demonstrated by the tremendous amount of surface made necessary, requiring towers 60 to 75 feet in height, and in most cases using two such towers connected in series. Furthermore, the "hurdle" tower requires thorough wetting of all the surfaces, which can be accomplished only by extravagant use of absorbing oil, out of all proportion to the amount required for actual absorption. This means not only a large and useless investment in absorbing oil, when employing a foreign oil, but the cost of pumping this excessive amount of oil repeatedly to the extreme heights mentioned is an item of expense that does not seem to be entirely justified.

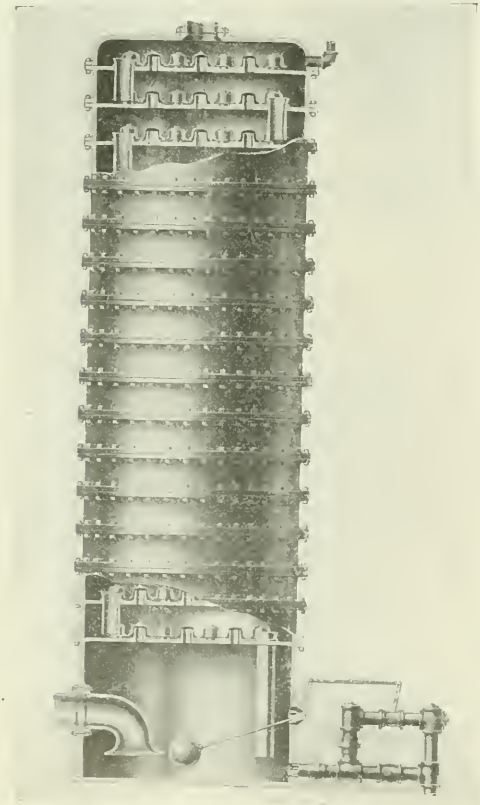

FIG. 3. CAP-AND-SEAL ABSORBER

Following is a striking illustration of the very satisfactory results obtainable with "bell-and-seal" absorbers as compared to towers filled with packing material for surface absorption such as the "hurdle" type. A prominent American concern recently desired to recover alcohol, acetone, etc., from the air-vapor mixture of these solvents, formerly wasted from an important drying operation. They first tried tall towers 25 or 30 feet in height and 4 feet in diameter, filled with packing material for surface absorption, using cold water as the absorbing medium. The results obtained were discouraging poor, indicating the need of much higher towers and an excessive amount of water to thoroughly wet the surfaces. We advocated a "bell-and-seal" absorber as being cheaper and far more efficient, and later installed a seven-tray absorber of the "bell-and-seal" type, measuring 24 in. square and standing about 5 feet high, equipped with Lummus patent atomizing caps. This small absorber effected practically complete recovery from the same volume of air and under the same conditions that previously applied to the rejected surface absorber. Water was used as the absorbing medium in the case referred to. It stands to reason, however, that exactly the same conditions apply, whatever the gas-vapor mixture or absorbing medium may be. Just as crude distilling colums, depending only on surface contact, have been largely abandoned in favor of "cap-and-seal" columns, so we believe will "hurdle" towers be abandoned eventually, for the more efficient and compact absorbers, and for quite similar and fundamental reasons.

Though we have no definite information as to close costs of "hurdle" towers, we are rather confident that their equivalent in the shape of "bell-and-seal" towers, in view of the limited number of trays or decks required, are no more expensive, at the same time offering the advantages cited, namely, while positive contact and minimum quantity of absorbing oil, with consequent economy in respect to the amount of absorbent required and the reduced cost of pumping.

Returning to our process, involving the use of tar as the scrubbing medium, it becomes very essential to use some efficient form of absorber, such as suggested above, for the obvious reason that an unlimited amount of tar per plant is not available. However, the quantity naturally produced has been shown by Dr. Carpenter, and demonstrated by English practice, to be sufficient for scrubbing the accompanying quantity of gas. Its use entirely eliminates the otherwise necessary investment in absorbing oil, which we understand costs in the neighborhood of 10 cents a gallon. Even the conservatly stated wash-oil requirement of 10 gallons per 1000 cubic feet of gas represents a considerable investment, especially when it is remembered that a large surplus

is required and frequent replacements are necessary to balance unavoidable losses.

We have designed a very simple form of absorber, which retains all the advantageous features of the "bell-and-seal" type, but excludes the rather expensive construction that usually applies to this type of tower. Our aim in this connection has been to develop an improved form of absorber, lending itself to economical construction throughout, so that even large sizes can be quickly made and without undue expense, at the same time entirely eliminating the intricate internal construction pertaining to hundreds of bells and seals required for the tower scrubber illustrated in Fig. 3. While we are not prepared to make positive claims in respect to this new type of scrubber, it appears, from estimates that we have been able to make, that it will be possible to reduce the cost of construction to less than one-half that applying to the usual "bell-and-seal" tower.

Advantages of Tar as the Absorbent

It may be well at this point to group some of the more obvious advantages applying to the use of tar as the absorbing medium:

a—The investment incidental to the use of a foreign absorbing oil is eliminated. This constitutes an important saving, especially when it is remembered that in the commonly described cyclic operation, a large excess of absorbing oil must be kept in readiness to take the place of the portion withdrawn from the process for special treatment to remove the naphthalene.

b—The appreciable and unavoidable loss of absorbing oil, requiring periodic replacement, is prevented by the use of tar absorbent in the non-cyclic system as suggested.

c—The toluol content of the original tar is recovered, as well as the portion obtained from the gas, and this is accomplished with one application of heat, without additional apparatus or operations.

d—The accumulation of naphthalene and other objectionable heavy oils in the tar becomes of no consequence, because the tar is used but once. This removes the necessity of elaborate chemical control and periodic external treatment of the absorbent for removal of the naphthalene, etc.

e—Should it now or later be required to recover the carbolic oil present in the tar, this may be accomplished simultaneously with the stripping of the light oil. Other methods of procedure exclude the tar and therefore would require additional equipment and use of heat should the tar constituents become of great importance.

f—As large and small gas plants produce tar in proportion to their gas output, the process becomes applicable to plants of whatever size, and similar types of apparatus would apply to recovery from water-gas, as well as from coal-gas and all other sources.

g—The entire elimination of an external absorbing oil removes the serious situation that would result in the event of a shortage of "straw" or tar oils required for unlimited development of the cyclic "absorbing and stripping" process.

h—The light oil produced by the proposed process would not contain absorbing oil requiring separation and return to the cycle. Therefore this light oil could be shipped to a central refinery without involving loss of absorbing oil.

i—No shut-downs would occur, due to delayed shipments of absorbing oils. Elimination of any important dependence on overtaxed transportation facilities, except for out-going concentrates, is thus assured.

Lummus-Hirzel Stripping Still

Accompanying Fig. 4 illustrates the Lummus adaptation of the so-called Hirzel stripping still, employing high-pressure steam in closed coils for maintaining a required temperature within the still, and with superheated steam injected into the lower chamber of the apparatus to assist evaporation of the light oil by repeated contacts through the large bell seals, as shown. It hardly needs to be explained that the so-called "benzolized" tar is admitted to the top chamber of the still and is caused to flow downward from chamber to chamber, counter-current to the upward passage of steam and vapor bubbling through the bell seals. The vaporized light oil, together with steam, passes over to a condenser, in which the mixture is condensed and cooled, and the light oil subsequently separated by means of a gravity separator. The "de-benzolized" tar, as pre-

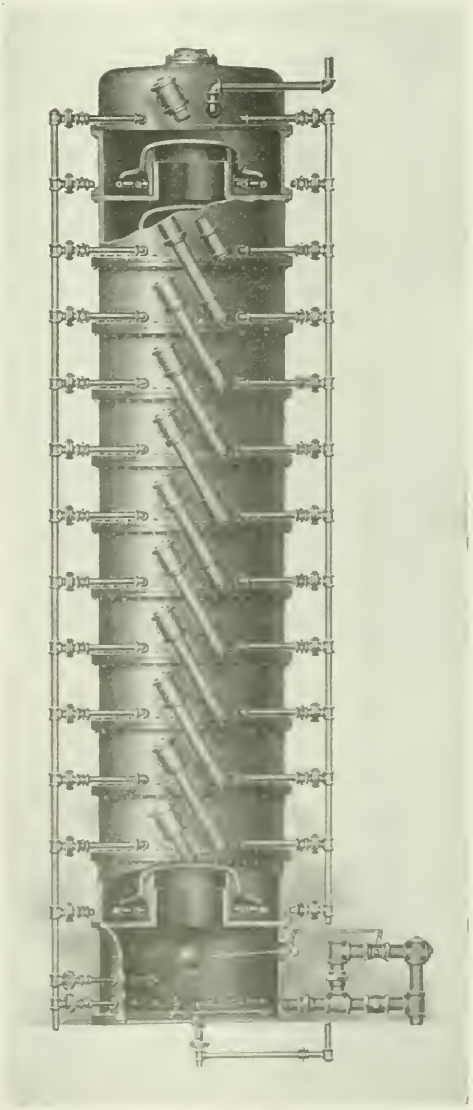

FIG. 4.—STRIPPING STILL

viously explained, issues from the lowest chamber of the still, and, after giving up its heat to the incoming "benzolized" tar, through a suitable heat interchanger, has completed its usefulness and is ready for sale or other disposal, as particular circumstances may determine.

Hirzel has quite properly pointed out that the above is not essentially a distilling operation, but rather one of separating a comparatively volatile body from one of low volatility by means of evaporation. On this account, a relatively constant temperature is maintained throughout the series of chambers, this being contrary to conditions favorable to true distillation, in which case the temperature decreases from the bottom toward the top of the column, corresponding to the rate of increasing the percentage of the low-boiling component in the ascending vapors. The Hirzel apparatus, therefore, is merely a convenient form of evaporator, for exposing the "benzolized" tar to heated surfaces simultaneously with repeated contacts with superheated steam and its associated light-oil vapor. Instead of placing pressure steam-coils within the respective chambers of the still, the tar may be superheated prior to its admission to the top chamber of the still. This procedure undoubtedly permits of simplifying construction somewhat, but has the disadvantage of being wasteful of steam. Under the most favorable conditions there is sure to be loss of superheat before the tar enters the column, and the temperature within the column must be maintained by an excessive use of steam injected at the bottom chamber. It is far more economical to supply the required superheat within and distributed throughout the column exactly at the points where it is needed. Furthermore, we have devised an improved design of the Hirzel type of still, simplified in respect to construction without losing any of the desirable features mentioned.

Lummus Direct-Fired Stripping Evaporator

During the year 1913 we carried on experiments on a semi-commercial scale to ascertain the behavior of certain gas tars when subjected to continuous superheated-steam distillation for the removal of the light-oil fraction. The apparatus comprised a modification of the Hirzel internally steam-heated still, and test runs were made, using both coal and water-gas tars. The results obtained conclusively proved the practicability of handling tars in this manner as opposed to the usual American practice of using direct-fired batch stills. It was found possible to completely remove the light and heavy oils, leaving a hard residual pitch; and the troublesome boiling-over habit, common to all batch tar stills, was entirely eliminated. But unfortunately one great disadvantage presented itself in too prominent a manner to be overlooked. The consumption of steam, both as superheated steam and pressure steam within the coils, was so great as to affect seriously the possibility of an extensive application of this otherwise very satisfactory procedure. We call attention to our experience in this connection, as conditions applying to all steam stripping processes appear to be identical to those encountered by us in respect to continuous distillation of tar with steam. Under the most favorable conditions, employing all possible heat economizers, we still found that the excessive consumption of steam constituted an item of expense that will at least bear thoughtful investigation.

In view of the above, we have been led to devise a new type of stripping still, which includes all the advantages of continuous operation without requiring the use of an excessive amount of steam. Furthermore, the design finally arrived at is very simple as compared to the Hirzel still and promises to be comparatively inexpensive. Accompanying Fig. 5 illustrates in a general way the arrangement of apparatus suggested. The "benzolized" tar, admitted at *A*, is made to flow in a very shallow stream throughout the length of the horizontal direct-fire-heated evaporator, as shown. Vertical diaphragms, with openings at alternate sides, are used to prolong the path of the tar over the heated surface. The "de-benzolized" tar issues at *B*, the sensible heat of which is utilized in warming the "benzolized" tar prior to its entrance into the evaporator at *A*. The residual tar, free of light oil, has thus, as before stated, served its entire useful purpose, so far as the recovery of toluol is concerned. Note that the "benzolized" tar enters at

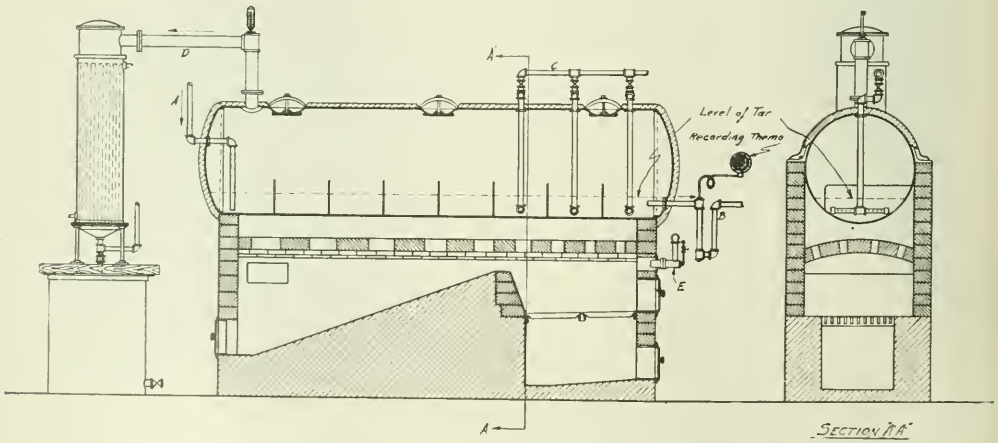

FIG. 5. DIRECT-FIRED CONTINUOUS STRIPPING EVAPORATOR

the cool end of the evaporator and the "de-benzolized" tar leaves at the hot end, with consequent counter-current advantages. Pipes marked *C* indicate means for injecting live superheated steam in the last three compartments, as possibly required in the event of desiring to remove the heavy as well as the light oils from the tar. The light-oil vapors pass through *D* to the condenser, to be condensed and cooled, ready for subsequent toluol concentration and refining. The evaporator may be heated by means of a coke fire used in conjunction with a tar burner, to permit reasonable regulation of temperature to avoid coking the tar. Should it appear desirable in some cases to operate at favorable low temperatures, a vacuum may be maintained within the evaporator by means of a vacuum pump attached to the outlet of the condenser. The small amount of steam required to operate the vacuum pump would not be of serious consequence. However, even this slight complication would not be required except perhaps in the event of carrying the evaporation to the point of producing a hard pitch.

Accompanying Fig. 6 illustrates the Lummus system of absorbing and stripping, the same in principle as indicated by Fig. 2, but substituting our direct-fired striping evaporator for the Hirzel type of steam-heated stripping still. In this case we do not attempt to utilize the heat of condensing the light-oil fraction, as the incidental saving does not seem to warrant the necessary apparatus complications. This apparent disregard of economy seems justifiable, due to the low cost of direct firing and the excess furnace heat available in spite of the most careful regulation of firing. On the other hand, the high pitch sensible heat of the residual tar is used for heating the incoming "benzolized" tar, as shown.

The apparent advantages of this direct-fired stripping evaporator may be enumerated as follows:

(a) The simple brick settings and inexpensive plate construction would seem to indicate a very low cost for this equipment as composed to that of the steam stripping stills.

(b) The total elimination of steam-heating and evaporating insures a marked reduction in operating expense, especially as coke and tar could be used as fuel.

(c) The convenient and easily understood operation is best adapted to labor conditions now obtaining at most gas works.

(d) Many boiler shops could turn out the evaporator shells quickly and in quantities. The Hirzel stills, involving castings and machine work, would prove a source of much more serious delay.

It must be admitted, in fact it is an assuring feature, that direct-fired continuous tar evaporators have been successfully employed in Europe. We are informed that their operation is simple and convenient, and results in respect to light-oil recovery are satisfactory. So again we merely suggest an improved form of apparatus that is not entirely new and untried in the sense of involving risk of unforeseen difficulties. Furthermore, we would not recommend the use of this still for "benzolized" straw-oil resulting from the cyclic process. The tendency to evaporate the lower-boiling portion of the absorbent would be, in our opinion, a serious objection, which, however, does not in any sense apply in the case of "benzolized" tar, which makes but one passage through the system.

Summary of Recommendations

Briefly summarizing the above article, we offer the following recommendations in the hope of stimulating, to whatever extent may be within our power and ability, an intensive toluol production:

a—The immediate organization of a Government-controlled and directed machine to develop a sufficient toluol supply with the same spirit and effect with which it is developing an army.

b—The prompt utilization of all available toluol sources and the simultaneous development of new sources to meet an ultimate requirement far beyond to-day's popular though erroneous conception.

c—More simple and efficient recovery methods and equipment, to conserve our limited resources against the possibility of a long and exhausting struggle.

d—Specific recommendations in respect to the "absorbing and stripping" process, including the use of tar as the ideal absorbent and more economical types of absorbers and stripping stills.

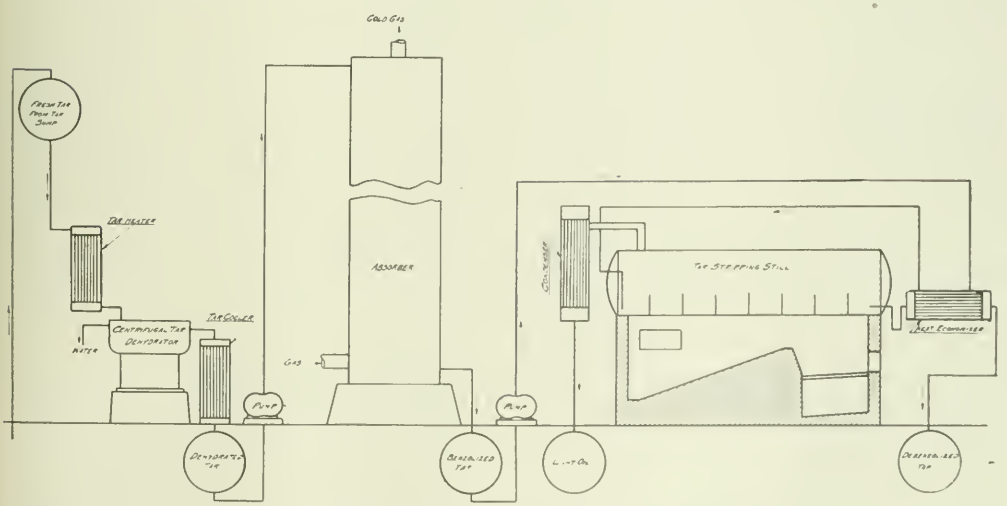

FIG. 6.—ABSORBING AND STRIPPING SYSTEM WITH DIRECT-FIRED EVAPORATOR

e—A thorough investigation of the real effect of the presence of paraffins on the manufacture of munitions, together with an educational campaign that may be required to overcome unfounded prejudice against paraffins.

f—Economical methods of munitions manufacture, especially to avoid waste of toluol, that the limited supply may be conserved to the utmost.

g—Finally, that there may be a country-wide awakening to the fact that our present insufficient toluol supply, unless quickly and effectively remedied, means defeat. This certainly is sufficient cause for grave concern, demanding utmost foresight and concerted, energetic action.

In conclusion, may we state that our recommendations, though intended to be highly practical and conservative, do not anticipate a hurried acceptance without careful preliminary investigation. The most we ask is a thorough consideration of our various suggestions, to be followed, if it appears warranted, by minor plant installations to definitely determine the degree of utility and dependableness of methods and equipment outlined. We also hope that sufficient publicity of our broader general plans may be realized for whatever good may result from our attempt to analyze existing conditions and to assist in stimulating a greater appreciation of the stupendous task that confronts us as a Nation.

It can hardly be said that we have taken ourselves too seriously. The occasion surely demands plain-spoken views and a pooling of experience and efforts, by which alone can we attain success. We recognize a duty in making known thus definitely such services as in our opinion we are best prepared to render.

The Walter E. Lummus Co.
Boston, Mass.

Synopsis of Recent Metallurgical and Chemical Literature

Temperature of Liquid Steel.—At the November meeting of the Faraday Society, in London, Mr. COSMO JOHNS spoke on "The Determination of the Temperature of Liquid Steel Under Industrial Conditions." Pointing out that skilled observers, with the aid of blue glass, were able to distinguish differences of 15 deg. C. when steel was flowing into a ladle, and that observers watching the same steel running into the ingot mold could distinguish temperature differences of about 10 deg. apparent, it was clear that any system of pyrometry to justify adoption must be able to record apparent temperatures with 5 deg. ± as the permissible variations. The system adopted, after much preliminary work, was the use of optical pyrometers using monochromatic light, and these had now been used in regular works practice for nearly four years. It was concluded as a result of this experience that concordant results of the required degree of accuracy required carefully trained observers, and the adoption of standard conditions of observation. Casual observers without knowledge of the many sources of error might easily obtain readings which departed 50 deg. from a correct reading. Observations must be made on the windward side of a launder down which steel was flowing from the furnace. If a value for the average temperature of that particular cast of steel was required, in order to determine its variation from the "normal" adopted for that particular practice, an observation of the center of the exposed side of the stream as it falls over the open end of the launder into the ladle when half the contents of the furnace had run out gave the best results. Such streams gave small but consistently different readings at the top, middle and bottom of the exposed side. The stream as it issues from the furnace taphole rises regularly in temperature as the successively hotter layers run out. The slag follows the same rule, but though serial readings obtained near the taphole have given much information as to the temperature gradient within the bath in the open-hearth furnace, it has not been found possible so far to explore the extreme ends of the gradient. That it is extremely steep near the surface of the bath is very probable, from the fact that it is in contact with the intensely hot flame of the furnace, and from the fact that under very favorable conditions the purest quartz sand has been fused, when floated on the surface of the bath, to a viscous fluid. Only "clean" surfaces of steel, free from oxide films, are suitable for observation, and these must of necessity be either rising in temperature, if flowing from the furnace, or falling in temperature if it is flowing from the casting ladle. Any temperature determination of liquid steel in open-hearth practice possesses no significance unless the relative time at which the observation was made is recorded. Owing to the importance of determining the softening or fusion range of the refractories, observations were made on the temperature of the interior of the furnace walls. As it was impossible to secure "black body" conditions, care was taken that the surfaces observed were "free radiators." These observations were therefore made after the furnace had been tapped. The gas was shut off and the door through which the pyrometer was sighted was lifted until wide open. Under these conditions every detail inside the furnace was visible: the joints in the brickwork, the junction of the sand banks with the side walls, port openings and places where wear had occurred, could all be perceived. Patches of new bricks could easily be distinguished from the adjoining old brickwork owing to their higher emissivity, though obviously at the same real temperature. It was suggested that if the emissivity of new silica bricks could be experimentally determined at 1650 deg. C. a very useful datum point would be available from which the emissivities of the surface of the slag and the seasoned bricks could be calculated. The emissivities adopted are tentative, and merely represent what best accords with the facts. Pyrometer readings of steel flowing from the ladle into an intermediate trough into the molds are tabulated, and the effect of oxide films with their higher emissivity is clearly indicated. It is concluded that under exceptionally favorable conditions a trained observer can repeat his readings with a variation of 2.5 deg. ± apparent while the variations in the observations discussed in the communication are something better than 5 deg. ±.

Hardening of High-Speed Steels.—At the November meeting of the Faraday Society in London, Prof. J. O. ARNOLD (University of Sheffield) spoke on "Pyrometry Applied to the Hardening of High-Speed Steels." He said the advantage of pyrometrically controlling the hardening of high-speed steel was a matter of common knowledge, and the most usual and best average temperature was 1300 deg. C. The practice at Sheffield University was to immerse the tool to be hardened in a

bath of fused barium chloride melted by a current which passed through two iron electrodes. This secured perfect regularity of temperature. The tools were then quenched in air, oil, or water.

Experiments were described in which five different pyrometers were used simultaneously; the Féry thermoelectric radiation pyrometer, the Féry bi-metallic spiral spring pyrometer, the Foster base-metal thermocouple, a modified Wanner radiation pyrometer, and the Mésure and Nouel, which Dr. Arnold favored very much, but in which the personal element was important. Using these different instruments and employing different observers, a grand mean temperature of 1296 deg. C. was arrived at, which was a tribute to the accuracy and reliability of the various methods of getting good observations. Dr. Arnold concluded by describing some observations that he had made on the casting temperature of steel tapped from an open-hearth furnace. The evidence of the results showed that such observations could be made reliable.

Potash from Feldspar.—In the Bulletin of the Institution of Mining and Metallurgy, Dec. 13, 1917, E. A. Ashcroft describes experiments on the production of potash from feldspar by an interesting method. He has worked out an industrial process and gives cost figures. In the process, orthoclase or microcline feldspar is dry crushed to 100 mesh (I.M.M.) in an iron mill and mixed with its own weight of pure dry common salt and then heated to 900-1000 deg. C. for two hours out of contact with air or moisture, or furnace gases carrying such air or moisture.

The sodium base of the salt displaces the potassium base of the feldspar strictly according to the equation:

$$2NaCl + K_2OAl_2O_3(SiO_2)_4 = Na_2OAl_2O_3(SiO_2)_4 + 2KCl.$$

If the temperature has not exceeded 1000 deg. C., and if moisture and air have been carefully excluded, the author states that the product will be found to consist of finely divided insoluble sodium feldspar (albite) and a mixture of quite neutral and freely soluble sodium and potassium chlorides. These chlorides may be readily lixiviated in water and are easily separated from each other by fractional crystallization.

The extraction of potash obtainable by this means from a sample of feldspar carrying upwards of 10 per cent K_2O will be in the neighborhood of 85 per cent under the conditions above stated. There is no loss by volatilization, and the weights of residue and salt will be found to correspond with the equation.

The experiment can be carried out in a large porcelain crucible (covered), or equally well in a sealed iron or nickel receptacle. Metals are not attacked so long as air and moisture are absent. These containers may be heated in an ordinary assay muffle for the experiment. If metal containers are used, it will be found that only on the outside of the vessel is there any attack, and this is due to air in the muffle. If air and moisture are excluded from the muffle, and a reducing or inert gas substituted, the containers will be very durable.

The author has independently discovered and studied this reaction, but he gives credit of priority for the discovery of the displacement of potash by soda obtained from salt to E. Bassett, who in 1913 patented in the United States and Canada a process based on the same reaction. The author has found that Bassett overlooked the necessity of excluding air and moisture. The author recommends the following as an emergency outfit: A standard bench of large "D"-shaped gas retorts (having 8 retorts to the panel and 10 panels, each panel having its own producer), and all the retorts inverted and provided with new metal end pieces of simple design. The whole furnace outfit is complete for no less than 50 tons potassium muriate of 80 per cent quality per day. That is as much potash as can be recovered from all the 300 blast furnaces in England put together, and assuming all that source of potash to be made available by means of expensive equipments of fume collectors and precipitators.

The author estimates that in normal times the 80 per cent salt will not cost 7*l.* per ton and not more than 15*l.* to 20*l.* even under war conditions. He says that any potash process with feldspar as raw material, if it is to be successful on an extensive scale, must stand or fall by a single product.

The whole problem then changes its aspect from a hopelessly complicated to a very simple economic problem, easily comparable with any simple mining venture.

The desirata for such an undertaking may be stated thus:

(1) Raw material in extensive deposits which can be quarried cheaply.

(2) Reasonably high and uniform potash content of feldspar.

(3) Water-borne freights for supplies to and from quarries.

(4) A simple and cheap process with reduction works on the quarry sites and not consuming acids or any other expensive materials.

All these desiderata are realized in the extensive deposits in Sutherlandshire, and, no doubt, they can be realized quite as favorably in many other parts of the world, in selected localities, if the same simple aims are kept in view, and the principles and process described are applied.

In New Zealand, in Australia, in Canada, and in parts of the United States, in Portugal, in Italy, and in other places there are favorable deposits of pegmatite feldspars, which lead me to anticipate that this source of potash supply may yet fill a large part of the world's requirements.

All consideration of by-products in such schemes should be a secondary thought, and should not form an essential part of the scheme. The author does not doubt that in some cases the treated feldspar may find useful applications and so add to the returns, but it must not be depended on for the results of any such enterprises.

When Are Chemical Results Patentable.—An interesting discussion of a decision handed down by Judge R. E. Lewis in the Eighth Circuit Court of Appeals in Chicago was given in the Chicago Chemical Bulletin for December. The suit was between the Corona Chemical Company and the Latimer Chemical Company. The discussion was as follows:

"The judge has made the ruling that the every-day

knowledge of the chemist which may prompt the execution of a successful experiment is not inventive genius. That the raising of the efficiency in degree only of any process without the accomplishment of any new function (if this efficiency is brought about by common knowledge of the chemist, his shop practice), this improvement is not patentable. This raises for the chemist the whole problem of what constituted new and useful improvement in the art of chemistry. In other words, what is a patentable invention in chemistry? This matter is of very great importance at the present time, because it is obvious that the whole subject is not clearly defined for the courts of America, and it is surely in the interest of chemists generally to define invention or discovery of a patentable nature in the chemical art rather than to require this definition at the hands of our American judiciary. Why not define it now rather than leave the matter in the hands of the lawyers and judges of our country and have forced upon us definitions, ruling limitations which may be troublesome or even disastrous to our fraternity?

Recent Metallurgical and Chemical Patents

Production of Oxalic Acid.—A process for the production of oxalic acid is patented by C. T. THORSSELL and H. L. R. LUNDEN, of Gottenborg, Sweden. The process relates to the production of oxalic acid from sodium oxalate, which is mixed with sodium carbonate and a little caustic soda.

"Oxalic acid and sulphate of sodium are obtained from the oxalate of sodium when sulphuric acid is added to the mixture of the three first-mentioned salts, and the sodium carbonate and the caustic soda are also transformed into sulphate of sodium. But this cannot be carried out conveniently in one operation, as acid oxalate of sodium precipitates and to get this transformed into oxalic acid so great a surplus of sulphuric acid would be needed that all the sodium would be present in the form of acid sulphate and there would still be a surplus of free sulphuric acid.

"By dividing the reaction in two parts or stages of treatment it can, however, be carried out with the desired result. Thus in the first stage the oxalate of sodium is transformed into acid oxalate of sodium and neutral sodium sulphate, and the sodium carbonate and the caustic soda are also converted into neutral sodium sulphate by means of a solution containing acid sulphate of sodium and sulphuric acid, which solution may be conveniently obtained from the second stage of treatment, thus making the process a continuous one.

"In the second stage the obtained acid oxalate of sodium is treated with sulphuric acid, whereupon oxalic acid and a solution of acid sulphate of sodium are obtained together with sulphuric acid, which may be used in the first stage of the repeated operation for the solution of the oxalate. Thus, in the first stage a solution obtainable from a previous stage and a solid substance (from the oxalate furnaces) are used, and a solution (neutral sulphate, forming the finished article) and a solid substance for subsequent use in the second stage are obtained. At the second stage a liquid (sulphuric acid) and a solid substance from the first stage are used, and a solution for subsequent use in the first stage, and a solid substance (oxalic acid=end product) are obtained.

"The finished oxalic acid must be washed with water and recrystallized so that it becomes perfectly pure, and besides it is advantageous to wash the acid oxalate a little, before it goes to the second stage. These washing liquids may be utilized without evaporation. The sulphate of sodium as well as the oxalic acid crystallize with water, and therefore a great quantity of water must be utilized in the operation. It is true that a little water is brought in with the sulphuric acid and that smaller quantities are formed when the carbonate of sodium and the caustic soda are converted into sulphate, but still the greater part must be added in the form of washing liquids. The method of working is thus made a little more complicated. (1,251,938, Jan. 1, 1918.)

Extraction of Rosin and Turpentine.—Improvements in the extraction of rosin, turpentine and oils from resinous wood are patented by JOHN E. TEEPLE, of Montclair, N. J. They comprise a process of extraction from resinous wood such as lightwood, stumps, pine slabs, etc., wherein such wood is heated and treated for a time in simultaneous contact with water and with spirits of turpentine, both the water and the spirits of turpentine being at their joint boiling point (the boiling point of the mixture) and such heating being conducted without substantial escape of vapors and the contact being either with condensing liquids or with a mass of each liquid. The extracted matters are removed together with water and solvent; and the wood is steamed to recover adhering solvent. (1,252,058, Jan. 1, 1918.)

By-products from Mine Water.—WM. M. PARKIN of Pittsburgh, Pa., patents a process of treating mine water containing sulphuric acid and iron salts. Water issuing from mines and particularly coal mines is a weak but highly corrosive solution containing acid, and is detrimental to fish life as well as destructive to submerged metal work, such for example as tanks, pipes, etc. These mine waters generally contain considerable free sulphuric acid, together with more or less aluminium salts. According to the patent it is proposed to treat these mine waters with calcium carbonate, in amount sufficient to neutralize all the free acid and to react with most of the iron salts. A precipitate is formed containing basic iron sulphates which is separated from the remaining liquid and heated to a temperature between 179 and 338 deg. C. producing a finely divided pigment. (1,251,564, Jan. 1, 1918.)

Production of Sulphite Acid Liquor.—G. D. JENSSEN of New York City patents a system of producing sulphite acid liquor in which the function of the absorbing towers may be changed at will without affecting the efficiency of the operation, and in which the process is a continuous one. A diagram of the apparatus is shown in Fig. 1. The operation is described as follows:

"In operating the system with the tower 1 as a strong acid liquor tower, the traps 16, 20, 21 and 51 are closed, also the valves 24, 34, 37, 28 and 42, and the traps 12, 19, 22 and 50 are opened, also the valves 25, 33, 38, 43 29.

"The sulphuric dioxide gas flows into the pipe 13,

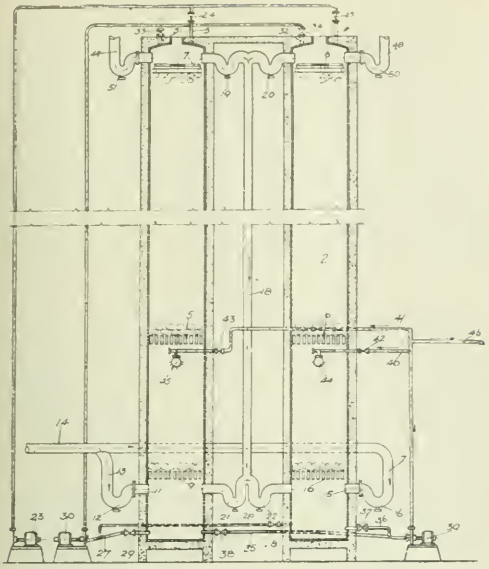

FIG. 1. DIAGRAM OF ACID SYSTEM

through the trap 12 and inlet pipe 11 to the tower 1 under the grate 9 and the tower 1 thus becomes part of the communicating passage from the gas plant for the initial and following flow of gas to the tower 2; which is the primary tower in the process of producing the acid liquor. The gas reaching the tower 1 rises in said tower through the blocks on the grate 9 and through the limestone pieces on the grate 5 and flows out of this tower through the trap 19 into the pipe 18 and down said pipe and through the trap 22 into the tower 2 under the grate 10 and rises in said tower 2 through the blocks on the grate 10 and limestone pieces on the grate 6 meeting the water being fed into the tower through the inlet pipe 4 as the said water trickles through the limestone and blocks. The spent gas exhausts through the trap 50 and pipe 48, being during the continuation of the process used in the two towers previous to its escape to the atmosphere.

"The weak acid liquor in the lower end of the primary tower is discharged through the pipe 26 to the acid liquor pump 30, from which it is forced up to the inlet pipe 31 and this weak acid liquor trickles down through the limestone pieces and blocks in the tower 1 and is met by the rising gas, which it largely absorbs, materially strengthening the acid liquor. The acid liquor flows out from the lower end of the tank 1 through the pipe 35 to the acid liquor pump 39, from which it is forced up to the pipes 41 and 46, a considerable quantity of the liquor flowing again into the tower 1 above the blocks and missing the limestone and thus apart from the latter absorbing the sulphur dioxide, so that the percentage of sulphur dioxide can be accurately gaged, this being regulated by the valve 43.

"To reverse the functions of the towers, 1 become the weak acid liquor tower and 2 the strong acid liquor tower, therefore the traps 16, 20, 21 and 51 are opened, also the valves 24, 34, 37, 28 and 42, and the traps 12, 19, 22 and 50 are closed, also the valves 25, 33, 38, 43, 29. Now the water is fed into the tower 1, and 2 becomes a communicating gas passage to tower 1 in the initial and following flow of gas thereto.

"The primary tower 1 receives its charge of gas from 2 which gas is absorbed by the trickling water and the weak acid liquor produced pumped into tower 2, from whence it flows to the acid pump 39 through the pipe 36 and from there it is pumped up to the pipes 40 and 46, the sulphur dioxide strength being regulated by the valve 42 as already explained.

"It will be seen that the process in certain parts follows out well known and practical knowledge in this art, but it also is a radical departure from common practice, as there is always an intervening tower between the sulphur dioxide plant and the primary tower and yet the towers may be reversed at will, thereby eliminating the necessity of shutting down the plant for washing the towers, as they are flushed regularly in use by the systematic change over of their functions. Then again each tower is provided with the means of regulating the percentage of sulphur dioxide, which may be used no matter how the towers are changed in regard to their functions and this is important both in the duplication of the parts and the novelty of the means employed. (1,251,533, Jan. 1, 1918).

Sulphur Dyes.—Two patents have been issued to Heinrich Heimann of Dessau, Germany, on sulphur dyes. The patents are assigned to the Actien Ges. für Anilin Fabrikation of Berlin. The first patent relates to the production of sulphur dyes by the action of sulphur on a mixture of an amino-, diameno-, nitrohydroxy-, and amino-azo compound with a C-alkylated diamine of the benzene and naphthalene series. One example of the process is given, as follows:

12 parts of meta-toluylenediamine, 20 parts of amino-azo-benzene and 80 parts of sulphur are heated together during about four hours upon say 180-230 deg. C. and then during about 1 to 2 hours to say 230-260 deg. C. The melt thus obtained is rendered soluble in the usual way by treating it with a concentrated solution of sodium sulphide. The new dye may be separated as usually for instance by introducing a current of air; it produces on unmordanted cotton in a dyebath containing an alkali metal sulphide beautiful olive shades which are fast to washing and to boiling diluted acids. (1,251,368, Dec. 25, 1917.) The second patent relates to the same class of dyes produced by the action of sulphur on a mixture of nitro-amino-azo compounds with a C-alkylated diamine of the aromatic series. An example follows:

16 parts of meta-toluylenediamine, 20 parts of para-nitrobenzene-azo-alpha-naphthylamine and 100 parts of sulphur are heated together to say 180-220 deg. C. during about 2-4 hours; the mass is then further heated during about 4-8 hours to say 220-260 deg. C. The melt may be treated as given above in order to obtain and purify the new dye which produces on unmordanted cotton a very beautiful yellow olive fast to washing and to diluted acid.

In a similar manner from a mixture of meta-toluylenediamine with para-nitrobenzene-azo-beta-naphthylamine a dye can be obtained which upon textile fiber produces a beautiful yellowish brown is likewise fast to washing and to boiling diluted acids. (1,251,368, Dec. 25, 1917.)

Baily Automatic Electric Furnace for Heat Treating Shells

The Electric Furnace Company of Alliance, Ohio, has developed an automatic furnace for heat treating high explosive and shrapnel shells. The furnace is an adaptation of equipments of similar size that have been used for some years in the heat treatment of steel railway and motor car parts. It combines the accurate temperature control of electric furnaces and the uniform quenching produced by the automatic manipulating device and eliminates almost entirely the manual handling of the shells. The makers state that the first cost is of course more than that of fuel-fired manually operated furnaces, but on contracts of any considerable size the labor saving and the elimination of rejections readily pay for the equipment.

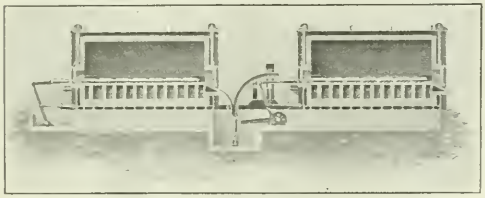

FIG. 1. CROSS SECTION OF TWO BAILY FURNACES WITH QUENCHING PIT

Fig. 1 shows a sectional view of two furnaces with a quenching mechanism located between them. The equipment includes a valve control pulpit and two contact-making pyrometers, one for each furnace. The couples of which are located in the discharge end of their respective furnaces, directly over the row of shells about to be discharged.

The operation of the equipment is as follows:

When the shells in the discharge end of the first furnace have reached the desired temperature, the heat from these shells actuates the pyrometer mechanism, closing a relay, and operating a solenoid on the radial dial switch of the pulpit, bringing the arm on the radial dial in contact with the switch, thus controlling the first movement of the equipment, which is the raising of the doors of the first furnace.

When the doors have been fully raised, the pusher on the first furnace pushes in the row of cold shells on the charging platform of that furnace, and, at the same time, pushes out of the discharge end the row of heated shells directly under the pyrometer tube. The pusher immediately reverses, and the doors close.

Meanwhile, the shells have dropped by gravity, nose down, on the quenching forks in the quenching pit, and immediately commence to rotate, the quenching water being turned on simultaneously and the shells sprayed from all directions, and internally.

At the same instant that the water is turned on, a time element, consisting of a disc operated by a constant speed motor through reduced gearing, is put in operation, and the water allowed to flow continuously for the predetermined time.

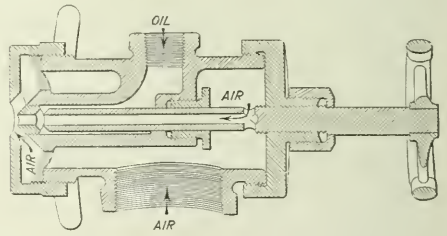
When the disk has made a complete circuit, the water is automatically shut off, the arms supporting the forks holding the shells move upward and deliver the shells in front of the pusher of the second furnace; the arms then return to their lower position ready to receive the next row of shells.

The quenched shells lie in front of the pusher of the second furnace until the shells in the discharge end of the second furnace actuate the pyrometer mechanism of that furnace, when a similar operation to the one described in connection with the first furnace takes place, pushing the quenching shells into the drawing furnace, and the drawn shells out at the discharge end. The only labor required is the placing of the shells on the charging platform of the first furnace, all other operations being performed automatically by the equipment itself.

A Fuel Oil Burner

In view of the difficulty of obtaining supplies of coal, attention is being turned in many quarters to other available fuels. In order to burn fuel oil it is necessary to have a burner, to atomize the oil and mix same with air. One type of fuel oil burner is shown in the accompanying illustration. It is known as the Coleman oil burner and is made by the Foundry Equipment Company of Cleveland, Ohio.

In this burner air is fed from the main air chamber through a hollow brass stem; the oil is fed around this circular stream of air, and at the end of the brass stem, which controls the oil supply, the oil is forced into the air stream at a sharp angle. This causes a breaking up of the oil into small particles and produces a primary mixing with the air. A second and larger



CROSS SECTION OF COLEMAN OIL BURNER

outer stream of air cutting through the primary mixture produces a further atomization and furnishes the proper combination of oil and air for complete combustion.

The burner was designed to overcome the clogging due to dirty and lumpy oil feeding through a small orifice. A quick means for clearing out any obstruction is provided by merely turning the hand wheel on the stem which opens the oil passage to full size.

The construction of the burner permits the feeding of a very small or large quantity of oil as well as complete control over the supply of air for combustion.

The burner connections provide for a ½-in. oil line and a 2-in. air line, giving a large range of feed of both oil and air. Air at 2 lb. and oil at 5 lb. per square inch are commonly used, but burners are in operation under a great variety of conditions as to pressure of oil and air.

The California Section of the American Chemical Society met on Jan. 12 in San Francisco and was addressed by Dr. Dorsey A. Lyon of the Bureau of Mines. J. W. Beckman is chairman of the Section.

Scrap Metal Briquetting Machines

A PATENT has recently been issued to Thomas Gilmore, Jr., of Brooklyn, N. Y., on a hydraulic briquetting machine for metal or mineral fines. The patent is assigned to the General Briquetting Co. of 25 Broad St., New York (1,247,667, Nov. 27, 1917). The machine is made by this company and is shown in the general view, Fig. 1. It is known as a horizontal three-stage briquetting press and is made especially for small capacities. It is a development of the Ronay system of metal briquetting which has been installed recently in many plants by the General Briquetting Co. The latter system is intended for larger plants where the output of scrap metal is over two tons per hour. The larger Ronay press is a vertical machine and is shown in Fig. 2. It will produce 6000 to 9600 lb. of briquettes per hour, of cast iron borings, 6-in. diameter and weighing 25 to 40 lb. each. On brass turnings it will produce 1500 to 7500 lb. per hour, the capacity varying with the density of the turning used for briquetting. Pressures from 23,000 to 33,000 lb. per square inch are applied on the briquettes.

The smaller horizontal type of machines, Fig. 1, have a cylindrical packing hopper provided with a swiveled lid. Material is introduced into the hopper intermittently. When the hopper is full the flow is checked and the lid closed, pressing the chips and curls together and getting rid of the surplus air. The operation of the low pressure pumps moves the plunger forward and packs the material into the mold shown at the right. The pressure is built up gradually, thereby allowing the escape of included air. Especial emphasis is laid on this feature.

When the material is thoroughly packed, the second stage begins. The full pressure is gradually built up until a maximum of 25,000 lb. per square inch is realized. A short interval is again allowed to assure permanent set. The pressure is removed. The third stage follows. By means of a lever the rear block of the mold is removed and a comparatively light pressure again applied. The plunge acts as an ejector and forces the finished briquette from the machine. The mold is closed, the plunger drawn back, the hopper opened and operation starts as before. This design is made in two sizes: "B" size, pressure 275 tons, making 6-in. briquettes, capacity $\frac{1}{2}$ to 1 ton per hour, and "C" size, pressure 125 tons, making 4-in. briquettes, capacity $\frac{1}{4}$ (and less) to $\frac{1}{2}$ ton per hour, depending in each case upon the nature of the material treated.

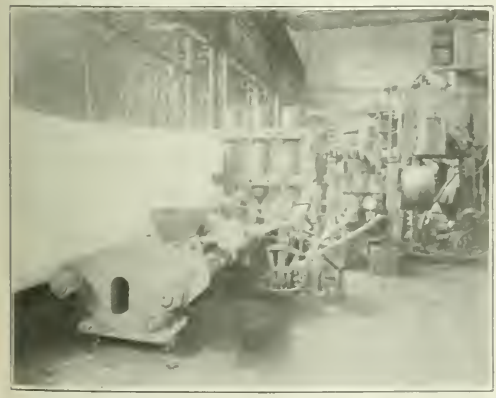


FIG. 1. TYPE "C" BRIQUETTING MACHINE

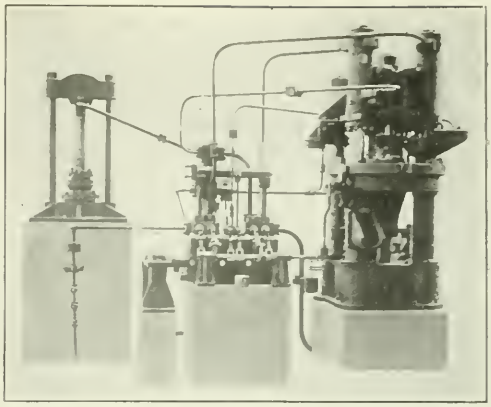

FIG. 2. TYPE "A" METAL BRIQUETTING PRESS, AUTOMATIC HYDRAULIC, SIX MOLD ROTARY PRESS

These presses have been used successfully on brass, aluminium, tin, zinc, lead, cast iron, steel, turnings and borings, sawdust, coal, coke, and various other residues and materials which were to be charged into a furnace. The use of fines in a furnace charge generally entails a heavy loss.

Bronze turnings when compressed into briquettes by this method only occupy one-sixth the original volume. When these briquettes are melted down a much smaller surface is exposed to the air, and the loss by oxidation is greatly reduced, as is also the time required for melting.

New Car Loader

A machine has recently been placed on the market by the Link-Belt Company, of Nicetown, Philadelphia, for loading all kinds of material into box cars. It is shown in the accompanying photograph.

It is a portable machine, driven by motor or gas engine, and handles the material delivered to it through the steel hopper, on a flat belt. On a recent

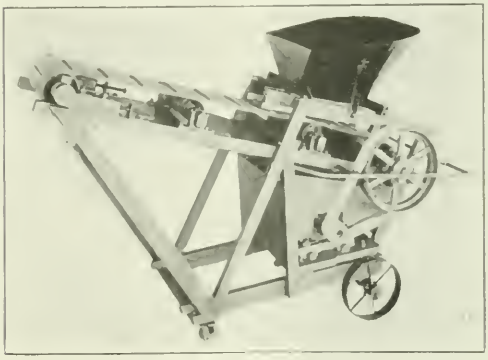

FIG. 1. NEW CAR LOADER

test it loaded 80 box cars in six days with two men. Its capacity is 80 to 100 tons per hour. In the present labor shortage the machine should prove especially valuable.

Personal

Professor WILDER D. BANCROFT of the department of chemistry of Cornell University, is in Washington, serving as technical adviser in the U. S. Bureau of Mines.

The following gentlemen have recently joined the staff of the Powdered Coal Engineering & Equipment Co., Chicago, Ill.; A. N. DETWEILER, consulting engineer; ALEX. L. FEILD, formerly assistant metallurgist at the Lake Superior Station of the Bureau of Mines; W. G. WILCOX, formerly superintendent of the Massena Works of the Aluminum Co. of America.

Dr. W. L. EVANS, a captain in the ordnance department, is organizing a large staff for research work and routine tests in the war department.

Dr. I. W. E. GLATTFELD has been appointed a member of the committee on the supply of organic chemicals for research during the war.

Dr. W. J. LENZ has severed his connection with the Lenz Apparatus Co., Inc., of 9 E. 16th St., New York, in order to devote his time to his manufacturing interests.

Prof. CHARLES E. LOCKE, professor of mining at Massachusetts Institute of Technology, has been appointed to give a course of 45 mining lectures during the last three weeks of January at the Missouri School of Mines, Prof. CARROLL R. FORBES of the latter school having entered military service.

Mr. F. C. NEWTON has resigned as general manager of the Newton Mfg. Company and is now assistant to the general manager of the U. S. Cartridge Company, at Lowell, Mass.

Mr. F. M. NOURSE has joined the advertising department of the Cutler-Hammer Mfg. Co. of Milwaukee in the capacity of technical writer. Mr. Nourse is a graduate of the University of Illinois, 1912, since which time he has been engaged in various branches of engineering work.

Professor W. A. NOYES spoke on the subject "The Development of a Career of Research" before the University of Illinois Section of the American Chemical Society on Jan. 15.

Mr. JOHN F. QUEENY, president of the Monsanto Chemical Company, 1800 South Second Street, St. Louis, Mo., has been elected general manager of the East St. Louis plant of the Commercial Acid Company, to succeed WILLIAM H. COOKE, the president, who has been called away to military service of the United States. The Commercial Acid Company is supplying the government with a large order of medical products.

United States Fuel Administrator Harry A. Garfield has announced the appointment of M. L. REQUA of California to handle oil matters for the United States Fuel Administration. Mr. Requa will have full charge of the activities of the Fuel Administration in connection with oil under the direction of Fuel Administrator Garfield. Since the organization of the United States Food Administration, Mr. Requa has been an assistant to Food Administrator Herbert Hoover. His transfer has been arranged with Mr. Hoover, who has consented to the change because of Mr. Requa's qualifications for his new position.

Mr. GUY E. TRIPP of New York, heretofore chairman of the Westinghouse Electric and Manufacturing Company, has been appointed by the War Department as Chief of the Production Division of the Ordnance Department, intrusted with the task of supervising and stimulating the production of all ordnance supplies. He has been given a commission as Colonel.

Dr. CHARLES H. VIOL, director of the Radium Research Laboratory of the Standard Chemical Co. of Pittsburgh, delivered an address on "Radium and Radio-activity" before the Philadelphia Section of the American Chemical Society on Jan. 17.

Mr. BURTON G. WOOD, formerly of the Monsanto Chemical Works of St. Louis, is now chief chemist of the Intravenons Products Co. of St. Louis, manufacturer of organic arsenic products, etc.

Mr. VICTOR YNGVE has been engaged as research chemist by the Oldbury Electro Chemical Company of Niagara Falls, N. Y., and will have charge of their research laboratory.

Prof. GEORGE J. YOUNG, recently professor of mining in the University of Minnesota, and previously in the Mackay School of Mines at Reno, Nev., has joined the editorial staff of the *Engineering and Mining Journal* as assistant editor-in-chief.

Current Market Reports

Chemical Market

Coal Tar Products.—The crudes for the most part have been quiet of late, but the intermediates have been in better demand than for some time heretofore. Prices in general are unchanged, although with an increased demand for the toluol intermediates, it would not be surprising to see a material increase in prices effective.

Benzol.—While there has been more business closed on contract over the year, there continues to be a good quantity of material offered at low prices. Spot material is not moving in large quantities, transactions in general being confined to small lots.

Toluol.—While a few producers of the intermediates have succeeded in securing releases of small quantities, there does not appear to be any inclination on the part of the authorities to grant general releases of material.

Naphthalene is in light supply; there has been quite a little business done during the past week with prices unchanged.

Benzoate of Soda supplies are light, and stocks for the most part are in speculative hands; prices are soaring by leaps and bounds. Only few producers are offering because of their inability to secure toluol.

Phenol.—There is but little available in the open market the Government having contracted for the majority of the output.

Aniline Oil.—A slightly improved inquiry, together with the scarcity of the necessary acids, has caused a slight advance in price.

Paranitraniline.—Some large sales have been consummated of late, but there continues to be large quantities offered and prices are unchanged.

Beta Naphthol.—There is a fair demand for the technical grade with prices varying but little because of the heavy production. Other grades are in light call and prices are on about the same parity as for some time past.

Aniline Salt.—There are a few offerings at a cent or two under the market, but the situation is quite firm on quantities of moment.

Metanitraniline.—Offerings are liberal and the demand light with prices unchanged.

Para Toluidine has been in better demand, but large factors have not as yet advanced prices, although it is said that some such plan is under way due to the toluol scarcity.

Ortho Toluidine.—Some large orders have been placed, but the price is unchanged.

Tolidin is in ample supply with the demand only fair and but little variation in the price range.

Anthracene is in light supply and large orders at goodly prices have failed to locate material quantities.

Para Nitro Phenol.—Large transactions have passed of late, but competition is keen and prices are unchanged.

Ortho Nitro Phenol continues to be the subject of inquiry from fur dyers and kindred lines, with prices firm.

Salicylic Acid has been more liberally produced, with the buying demand quiet and prices breaking considerably.

Diphenylamine has been in heavy demand, and but few are producing with prices advancing.

Para Amido Phenol has been produced liberally of late, competition is keen and prices have been reduced.

Heavy Chemicals.—The interval as is usual at this time of the year has been quiet but the extraordinary conditions that have prevailed this January have tended to create a still more uncertain condition. Transactions have mostly been for odd lots of material for prompt delivery. Contracts over the year have been neglected to a rather unusual degree. Improvement is looked for during the coming month as the middle of February is ordinarily the turning point.

Caustic Soda.—From the most speculative market in the chemical classification this market has assumed an aspect fully as quiet as any other chemical. Owing to freight difficulties sellers have been somewhat reluctant to quote forward positions but buyers have on the other hand shown but little desire to cover. Caustic soda is well held it is quite evident. Despite the lack of business prices have not declined and some material has commanded from 6½c up. Forward positions are generally obtainable at 6c.

Soda Ash.—This market has been more active than caustic but the total volume of business transpiring has not been very large. Stocks are well held and spot positions have generally commanded 3c., although the figure has been shaded a trifle from time to time. Export barrels have been in urgent request and it seems that export licenses have been granted probably to South American points.

Bichromate of Soda.—There has been a decided flurry in this market charged variously to speculative interests, and then, again, to an export order for some 250 tons concerning which there did not seem to be any definite information possible. In any event sales were rather frequent and passed as high as 20c. for spot. Producers seemingly thought the situation one that warranted higher prices for shipments from the works were advanced from 20c. and in some cases to 22c.

Bichromate of Potash.—In contrast this product has not been easily moved and there have been offers of spot material at 41c., although the general asking price is 43c. and 45c.

Calcium Carbide.—The demand continues far in excess of the supply, and sales, principally for export, are occurring at record high prices. The various sizes are selling at about the same price. Sales have occurred at high as 13½c. From 12½c. to 13½c. covers the market.

Acetic Acids.—The situation has revealed considerable firmness owing to the difficulty of securing raw materials, but there has not been a great deal of activity noted and consumers are rather inclined to hold off.

Cyanide of Soda.—The product has not moved well during the interval, and it has been possible to purchase prompt stocks at comparatively attractive figures. Generally regular sellers quote 43c. to 45c. as to shipping point.

Sulphuric Acid.—The acid situation continues to reveal the same degree of firmness previously noted, but there is not a great deal of activity noted. Some 66 degree brimstone acid has been offered at $40 sellers tanks works January shipment. In drums $45 is generally quoted. A lot of several hundred tons of 60 degree brimstone acid was offered at a New Jersey point at $40 drums for prompt shipment. Oleum has been offered at $75 prompt and $70 January shipment from works.

Nitric Acid.—So far there has been no pronounced movement in nitric acid. From various points there are offers of car quantities of the 42 degree material at 9c. The scarcity of carboys has tended to restrict shipment considerably.

Muriatic Acid.—Heavy government buying of late has created a very firm situation and prices are now much higher than any that have prevailed for a year. Carboys are so scarce that acid consumers have more difficulty in securing packages than the acid itself. Prices vary greatly according to seller and shipping point.

Bleaching Powder.—Slow train movements tend to restrict the market and at the same time tend to lower values. Bleach a month en route is not an attractive buy when fresh material is absolutely necessary. Shipments rolling have generally been available at about 2c. domestic drums but for prompt material from works producers have not been inclined to quote under 2½c.

The Iron and Steel Market

The weather has become the chief topic of conversation in iron and steel circles. The weather determines the volume of transportation and the iron and steel industry depends upon transportation. Fuel Administrator Garfield's order prohibiting the burning of fuel, with certain exceptions, Jan. 18 to 22, inclusive, and nine Mondays thereafter, created a furore in many manufacturing circles, but not in the iron and steel industry, where it was interpreted as a phase of the transportation situation. Some manufacturers stood aghast at the idea of their plants being closed by edict, but the iron and steel industry is used to strenuous things. Breaks in machinery that close plants are no less unexpected, individually, than was Dr. Garfield's order. It was obeyed by the steel industry as fully as physical conditions permitted.

The order was interpreted as permitting blast furnaces to operate, as they would be injured more or less by banking, and coke would be consumed without pig iron being produced, while the congestion in cars loaded with coke would simply be transferred from the neighborhood of production to the neighborhood of consumption. As to the steel-making units there was some question, but as a rule they closed. The rolling of steel ceased except as to exempted products. There was some accumulation of cold ingots, and a larger accumulation of Sunday metal, but there is no curtailment in the long run in the production of finished steel, for there is ample steel-making capacity to absorb the Sunday metal, and the ingots accumulated can be rolled in due course. As to the steel industry, the fuel order postponed the consumption of a great deal of fuel, but it did not effect a net reduction in the consumption. Rather there is in the long run an increase, by reason of the use of Sunday metal and cold ingots.

Transportation Governing Factor

More or less since late in November, 1916, and absolutely in the past few months the production of steel has hinged upon the production of pig iron, and the production of pig iron in turn has hinged upon the supply of coke, the chief restriction in the latter being the insufficient movement of the Connellsville product, next in order being a shortage of coal at by-product ovens. In any event it has been altogether a matter of transportation. Production of pig iron in 1916 was 39,400,000 tons, with several new furnaces completed during the year, and with still more new furnaces completed in 1917 the year's production was only about 38,600,000 tons. The production rate in December was about 34,000,000 tons, and the January rate has been still less. By this time the productive capacity must be close to and quite possibly in excess of 43,000,000 tons. The production of steel ingots in 1916 was 41,400,000 tons. The new capacity added in 1916 and 1917 is rated at over 8,000,000 tons, and could doubtless be counted upon for 7,500,000 tons in actual practice. That part of the 1916 production attributable to capacity in existence at the beginning of the year was fully 40,000,000 tons, hence capacity at the end of 1917 may be taken at 47,500,000 tons, but the monthly report of the American Iron and Steel Institute shows production in December, 1917, at the rate of only 37,000,000 tons. Production in January up to the time of the fuel order was at a still lower rate. All this restriction is shortage of pig iron, this in turn being shortage of coke and this in turn shortage of transportation.

The situation represents not a slight restriction but a great breakdown in the matter of transportation. Last year's coal production, almost adequate, was 544,000,000 net tons of bituminous coal and 100,000,000 net tons of anthracite, or 644,000,000 tons altogether. A liberal estimate is an average haul of 100 miles, since most industries have located close to their fuel. That is 65,000,000,000 ton-miles of freight movement, and in the five months ended last August the railroads conducted transportation at the rate of 425,000,000,000 ton-miles a year. The coal movement represents only 15 per cent of movement at last summer's rate, and under Government control, with various restrictions removed, the railroads are expected to do still better. Connellsville coke movement has lately been short by an average of about 75,000 tons a week, representing about 5,000,000,000 ton-miles of movement, or less than

one-eighth of one per cent of the railroads' normal capacity. The shortage of by-product coal represents probably a still smaller fraction.

The conditions described have been bad enough, but in recent weeks there has been the additional restriction of shortage of cars for moving finished steel, and then a large number of embargoes, with permits granted only occasionally. Despite the restriction in production caused by insufficiency of raw material, it has been impossible to ship the product, and finished steel has accumulated in warehouses and yards to such an extent that any considerable further accumulation is impossible, and departments are closing because they cannot ship their product.

In the circumstances there is no market to discuss and the trade thinks only of weather prospects. Steel shipments in January have represented only about half the capacity. With favorable weather, which cannot be many weeks distant, conditions may be entirely different. March is traditionally a record month for both pig-iron and steel production.

By Washington's edict of Dec. 29 the matter of iron and steel price revision will come up not later than March 31, but current events are manufacturing no testimony as to what should then be done. Cost of production at a time like this could not be used as a measure of what would be right prices in the future. One thing clear is that if Washington desires lower prices for pig iron and steel, the fair and efficient method of preparing the way is to seek first conditions that will permit orderly and economic production.

Non-Ferrous Metal Market

Friday, Jan. 25.—There has been very little activity in any of the markets during the past two weeks, and prices show little variation with the exception of tin which is still scarce and higher.

Copper.—The President has announced his approval of the recommendation of the War Industries Board that the maximum price for copper be continued at 23½ cents per pound f.o.b. New York until June 1, 1918. This price is subject to revision after June 1, 1918, upon the conditions, first, that the producers will not reduce the wages now being paid; second, that the producers will sell to the allies and to the public copper at the same price paid by the Government, and take the necessary measures under the direction of the War Industries Board for the distribution of the copper to prevent it from falling into the hands of speculators who would increase the price to the public; and, third, that the producers pledge themselves to exert every effort necessary to keep up the production of copper to the maximum of the past, so long as the war lasts. At the present writing it was difficult to buy electrolytic copper for February delivery. Casting copper is more freely offered. The jobbers' price remains at 24.67½ cents, New York.

Tin.—The tin market is unsettled and actual quotations are hard to give as no tin is offered for sale. The Emergency Fleet Corporation commandeered the pig tin stores in New York on Jan. 23, presumably for distribution to concerns having urgent need of the tin to finish war orders. The arrivals so far this month are only 1065 tons which is about one-fifth normal. England is still holding up shipping permits.

Lead.—The market has been very dull and the Trust price remains at 6.75 cents, with independents asking 7 cents. Very little metal is offered for sale. Transportation problems and the fact that some producers are sold up have combined to make the inactive market. Also, consumers are not bidding heavily.

Spelter.—There is not much to be said about the spelter market. Buyers do not show much interest and the market is very dull. The average quotation at New York now is about 7.82½ cents for Prime Western. Nothing has been done to fix prices on ordinary grades of spelter as yet and producers maintain that they cannot produce at a profit under 10 cents. The price on high grade spelter is adjusted by the Zinc Committee and War Industries Board.

Tungsten.—Scheelite has been offered more freely owing to arrivals from California and South America. Prices average about $24.50 for 65 per cent material.

Molybdenum.—The Canadian embargo on molybdenite has been raised and arrivals have been large, selling at $2.15 to $2.20 per pound for 85 per cent material.

Chromium.—Chrome ore is scarce and high prices are asked. Ferrochromium will probably go higher.

Quicksilver.—California material is offered at $130 per flask with Mexican at $125.

Other Metals

Aluminium, lb.	.36–.38
Bismuth, lb.	3.00–3.50
Cadmium, lb.	1.50
Nickel, electrolytic, lb.	.55
Silver, oz.	.87¾
Platinum, oz.	105.00
Palladium, oz.	130.00–135.00
Cobalt, lb.	3.25–3.50
Magnesium	2.00

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JAN. 24, 1918

Acetic anhydride	lb.	Nominal	
Acetone, drums	lb.	Nominal	
Acid, acetic, 28 per cent	lb.	05½ —	.06
Acetic, 56 per cent	lb.	11¼ —	.12
Acetic, glacial, 99½ per cent, carboys	lb.	.34 —	.35
Boric, crystals	lb.	13¼ —	.14¼
Citric, crystals	lb.	75 —	.78
Hydrochloric, C. P	lb.	Nominal	
Hydrochloric, 20 deg	lb.	Nominal	
Hydrochloric, conc., 22 deg	lb.	Nominal	
Hydrofluoric, 30 per cent, in barrels	lb.	.06½ —	.06½
Lactic, 44 per cent	lb.	.15 —	.15½
Lactic, 22 per cent	lb.	.05½ —	.06½
Nitric, 36 deg	lb.	.09 —	.10
Nitric, 42 deg	lb.	.09 —	.10
Oxalic, crystals	lb.	.44 —	.45
Phosphoric, 47 per cent-50 per cent crude	lb.	.07 —	.07½
Phosphoric, ref. 50 per cent	lb.	.26 —	.....
Picric	lb.	Nominal	
Pyrogallic, resublimed	lb.	3.15 —	3.25
Sulphuric, 60 deg	ton	—	.....
Sulphuric, 66 deg	ton	40.00 —	45.00
Sulphuric, oleum (Fuming), tank cars	ton	70.00 —	80.00
Tannic, U. S. P., bulk	lb.	1.30 —	1.35
Tartaric, crystals	lb.	.78 —	.80
Tungstic, per lb. of W	lb.	1.80 —	1.90
Alcohol, sugar cane, 188 proof	gal.	5.05 —	5.25
Alcohol, wood, 95 per cent	gal.	1.35 —	.....
Alcohol, denatured, 180 proof	gal.	.78 —	.80
Alum, ammonia lump	lb.	04½ —	.05
Alum, chrome ammonium	lb.	.18 —	.19
Alum, chrome potassium	lb.	.23 —	.25
Alum, chrome sodium	lb.	12½ —	.13
Alum, potash lump	lb.	Nominal	
Aluminium sulphate, technical	lb.	.01½ —	.02
Aluminium sulphate, iron free	lb.	.02¾ —	.03
Ammonia aqua, 26 deg. carboys	lb.	.20 —	.....
Ammonium carbonate	lb.	.11 —	.12
Ammonium nitrate	lb.	(Fixed price)	.14
Ammonium, sulphate domestic	lb.	07¼ —	.07½
Amyl acetate	gal.	5.25 —	5.40
Arsenic, white	lb.	.16¼ —	.16½
Arsenic, red	lb.	.65 —	.70
Barium carbonate, 99 per cent	ton	80.00 —	90.00
Barium carbonate, 97-98 per cent	ton	65.00 —	67.00
Barium chloride	ton	70.00 —	90.00
Barium sulphate (Blanc Fixe, powder)	lb.	.03½ —	.04
Barium nitrate	lb.	.09½ —	.11
Barium peroxide, basis 70 per cent	lb.	.31 —	.34
Bleaching powder, 35 per cent chlorine	lb.	.02½ —	.02¾
Borax, crystals, sacks	lb.	.07½ —	.08¼
Brimstone, crude	ton	Nominal	
Bromine, technical	lb.	.65 —	.70
Calcium, acetate, crude	lb.	Nominal	
Calcium, carbide	lb.	12½ —	.13
Calcium chloride, 70-75 per cent, fused, lump	ton	22.00 —	23.00
Calcium peroxide	lb.	1.60 —	1.70
Calcium phosphate	lb.	.30 —	.31
Calcium sulphate	lb.	—	.....
Carbon bisulphide	lb.	.07 —	.07½
Carbon tetrachloride, drums	lb.	.14 —	.16
Carbonyl chloride (phoszene)		—	.....
Caustic potash, 88-92 per cent	lb.	.83½ —	.84
Caustic soda, 76 per cent	lb.	.06½ —	.06¾
Chlorine, liquid	lb.	.15 —	.18
Cobalt oxide	lb.	1.40 —	1.50
Copperas	lb.	01¼ —	.01½
Copper carbonate	lb.	.45 —	.....
Copper cyanide	lb.	.75 —	.78
Copper sulphate, 99 per cent, large crystals	lb.	.09 —	.09½
Cream of tartar, crystals	lb.	.61 —	.63
Epsom salt, bags	lb.	03½ —	.03¾
Formaldehyde, 40 per cent	lb.	19½ —	.20
Glauber's salt	100 lb.	1.00 —	1.10
Glycerine, bulk, C. P	lb.	67½ —	.70
Iodine, resublimed	lb.	4.25 —	4.35
Iron oxide	lb.	.13 —	.15
Lead, acetate, white crystals	lb.	.17 —	.17½
Lead arsenate (Paste)	lb.	.15 —	.18
Lead nitrate	lb.	Nominal	
Litharge, American	lb.	09½ —	.11½
Lithium carbonate	lb.	1.50 —	2.00
Manganese dioxide, U. S. P	lb.	.70 —	.75
Magnesium carbonate, technical	lb.	.10 —	.10½
Nickel salt, single	lb.	Nominal	
Nickel salt, double	lb.	Nominal	
Phoszene, see Carbonyl chloride		—	
Phosphorus, red	lb.	1.60 —	1.70
Phosphorus, yellow	lb.	1.25 —	.....
Potassium bichromate	lb.	.43 —	.45
Potassium bromide granular	lb.	1.45 —	1.50

Potassium carbonate calcined, 85-90 per cent	lb.	.60 —	65
Potassium chlorate, crystals	lb.	.40 —	42½
Potassium cyanide, 98-99 per cent	lb.	Nominal	
Potassium iodide	lb.	3 75 —	3 80
Potassium muriate 80-85 p. c. basis of 80 p. c	ton	350.00 —	...
Potassium nitrate	lb.	.30 —	.32
Potassium permanganate (U. S. P.)	lb.	4.00 —	4.10
Potassium prussiate, red	lb.	2.60 —	2.70
Potassium prussiate, yellow	lb.	1.27 —	1.30
Potassium sulphate, 90-95 p.c. basis 90 p.c	ton	Nominal	
Rochelle salts	lb.	.39 —	39½
Salammoniac, gray gran	lb.	.15 —	.16
Salammoniac, white gran	lb.	.15 —	.16
Sal soda	100 lb.	1.25 —	1.30
Salt cake	ton	22.00 —	23.00
Silver cyanide, based on market price of silver	oz.	—	
Silver nitrate	oz.	.53 —	.55
Soda ash, 58 per cent, light, flat	100 lb.	2.95 —	3.00
Soda ash, 58 per cent, dense, flat	100 lb.	3.50 —	4.00
Sodium acetate	lb.	.16½ —	.17
Sodium bicarbonate, domestic	lb.	.02¾ —	.03
Sodium bicarbonate, English	lb.	—	
Sodium bichromate	lb.	.19½ —	.20
Sodium bisulphite, powd	lb.	.06¼ —	.06½
Sodium chlorate	lb.	.20 —	.22
Sodium cyanide	lb.	.42 —	.44
Sodium fluoride, commercial	lb.	.18½ —	...
Sodium hyposulphite	lb.	.02½ —	...
Sodium molybdate, per lb. of Mo	lb.	2.50 —	...
Sodium nitrate, 95%	100 lb.	4.50 —	...
Sodium nitrite	lb.	.30 —	.35
Sodium peroxide	lb.	.49 —	.50
Sodium phosphate	lb.	.04 —	.04½
Sodium prussiate, yellow	lb.	.37 —	.38
Sodium silicate, liquid (60 deg.)	lb.	.03½ —	.04½
Sodium sulphide, 30 per cent., crystals	lb.	.02¾ —	.03
Sodium sulphide, 60 per cent., fused	lb.	.04⅞ —	.05
Sodium sulphite	lb.	.05 —	.06
Strontium nitrate	lb.	.25 —	.35
Sulphur chloride, drums	lb.	.06 —	.06½
Sulphur dioxide, liquid, in cylinders	lb.	.15 —	.40
Sulphur, flowers, sublimed	100 lb.	4.05 —	4.10
Sulphur, roll	100 lb.	3.70 —	3.85
Sulphur, crude	ton	Nominal	
Tin bichloride, 50 deg	lb.	Nominal	
Tin oxide	lb.	.75 —	.90
Zinc carbonate	lb.	.22 —	.25
Zinc chloride	lb.	.10¼ —	.11
Zinc cyanide	lb.	Nominal	
Zinc dust, 350 mesh	lb.	.17 —	.18
Zinc oxide, American process XX	lb.	.13½ —	14
Zinc sulphate	lb.	.06 —	.07

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.35 —	.40
Benzol, 90 per cent	gal.	—	
Toluol, pure water white	gal.	Nominal	
Xylol, pure, water white	gal.	.35 —	.50
Solvent naphtha, water white	gal.	.17 —	.22
Solvent naphtha, crude, heavy	gal.	.13 —	.16
Creosote oil, 25 per cent	gal.	.33 —	.35
Dip oil, 20 per cent	gal.	.29 —	.30
Pitch, various grades	ton	8.00 —	20.00
Carbolic acid, crude, 95-97 per cent	lb.	1.05 —	1 10
Carbolic acid, crude, 50 per cent	lb.	.60 —	65
Carbolic acid, crude, 25 per cent	lb.	.35 —	.38
Cresol, U. S. P.	lb.	.18 —	20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.10 —	...
Alpha naphthol, distilled	lb.	1.60 —	...
Alpha naphthylamin	lb.	.58 —	.60
Aniline oil, drums extra	lb.	.26 —	.28
Aniline salts	lb.	.32 —	.34
Anthracene, 80 per cent	lb.	.50 —	.65
Benzaldehyde	lb.	4.00 —	4.50
Benzidine, base	lb.	1.75 —	1.85
Benzidine, sulphate	lb.	1.40 —	1.50
Benzoic acid U. S. P.	lb.	—	
Benzoate of Soda, U. S. P.	lb.	5.45 —	5.75
Benzyl chloride	lb.	1.75 —	1.85
Beta naphthol benzoate	lb.	7.00 —	8.00
Beta naphthol, sublimed	lb.	.85 —	.90
Beta naphthylamin, com	lb.	2.50 —	2.65
Diehlor benzol	lb.	.12 —	.18
Diethylaniline	lb.	4.00 —	5.00
Dinitro benzol	lb.	.34 —	.50
Dinitrochlorbenzol	lb.	.40 —	.42
Dinitronaphthaline	lb.	.55 —	.60
Dinitrotoluol	lb.	.55 —	.60
Dinitrophenol	lb.	.55 —	.57
Dimethylaniline	lb.	.57 —	.62
Diphenylamine	lb.	.85 —	1.00
H-acid	lb.	2.25 —	2.50
Metaphenylenediamine	lb.	1.85 —	2.00
Monochlorbenzol	lb.	.19 —	.22
Naphthalene, flake	lb.	.09½ —	.09¾
Naphthalene, balls	lb.	.10½ —	.10¾
Naphthionic acid, crude	lb.	1.40 —	1.50
Naphthylamin-di-sulphonic acid	lb.	1.00 —	1 10
Nitro naphthaline	lb.	.45 —	.50
Nitro toluol	lb.	.50 —	.55
Ortho-amidophenol	lb.	—	
Ortho-toluidine	lb.	1.00 —	1 20
Ortho-nitro-toluol	lb.	.75 —	1 00
Para-amidophenol, base	lb.	3.50 —	4 00
Para-amido-phenol, H. Cl	lb.	4 00 —	4 25
Paranitraniline	lb.	1.05 —	1 15
Para-nitro-toluol	lb.	1.50 —	1 60
Paraphenylenediamine	lb.	3.00 —	3 50
Para toluidine	lb.	2 25 —	2.50
Phthalic acid anhydride	lb.	4 50 —	6 50
Phenol, U. S. P.	lb.	.53½ —	.55
Resorcin, technical	lb.	6 00 —	7 00
Resorcin, pure	lb.	10.00 —	12 00
Salicylic acid	lb.	1.05 —	1 10
Salol	lb.	1.85 —	2 00
Sulphanilic acid	lb.	.32 —	.35
Tolidin	lb.	2 50 —	...
Toluidine-mixture	lb.	.75 —	.85

Petroleum Oils

Crude (at the Wells)

Pennsylvania	bbl.	3.75 —	...
Corning, Ohio	bbl.	2.80 —	...
Somerset, Ky	bbl.	2.55 —	...
Wonster, Ohio	bbl.	2.38 —	...
Indiana	bbl.	1.98 —	...
Illinois	bbl.	2.12 —	...
Oklahoma and Kansas	bbl.	2.00 —	...
Caddo, La., light	bbl.	2.00 —	...
Corsicana, Tex., light	bbl.	2.00 —	1.32
California	bbl.	.98 —	...
Gulf Coast	bbl.	1.00 —	...

Fuel Oil

New York	gal.	.11 —	...
Pittsburgh	gal.	.07½ —	.10
Oklahoma-Kansa	bbl.	1.50 —	2.35
Texas	bbl.	1 50 —	1.75
Los Angeles	bbl.	1.52 —	...
San Francisco	bbl.	1.45 —	...

Gasoline (Wholesale)

New York	gal.	.24 —	...
Boston	gal.	.25 —	...
Pittsburgh	gal.	.26 —	...
Chicago	gal.	.21 —	...
Oklahoma	gal.	.25 —	...
San Francisco	gal.	.20½ —	...

Lubricants

Black, reduced, 29 gravity, 25-30 cold test	gal.	.19 —	.20
Cylinder, light	gal.	.34 —	.35
Cylinder, dark	gal.	.33 —	.34
Paraffine, high viscosity	gal.	.36 —	.37
Paraffine, 903 sp. gr	gal.	.29 —	.30
Paraffine, .865 sp. gr.	gal.	.21 —	.22

Flotation Oils

(Prices at New York unless otherwise stated)

Pine oil, crude, f.o.b. Florida	gal.	.44 —	...
Pine oil, steam distilled, sp. gr. 0.925-0.940	gal.	.50 —	...
Pine oil, destructively distilled	gal.	.43 —	.53
Pine-tar oil, sp. gr., 1.025-1.035	gal.	.30 —	...
Pine-tar oil, double refined, sp. gr. 0.965-0.990	gal.	.35 —	...
Pine oil, light, sp. gr. 0.930, tank cars, f.o.b. works	gal.	.37 —	...
Pine oil, heavy, sp. gr. 1.025, tank cars, f.o.b. works	gal.	.26 —	...
Pine tar, thin, sp. gr. 1.060-1.080	gal.	.32 —	...
Turpentine, crude, sp. gr. 0.980-1.000	gal.	.40 —	...
Hardwood oil, f.o.b. Michican, sp. gr. 0.960-0.990	gal.	.21 —	...
Hardwood oil, f.o.b. Michican, sp. gr. 1.06-1.08	gal.	.19½ —	...
Wood creosote, ref. f.o.b. Florida	gal.	.31 —	...

Vegetable and Other Oils

Chioa wood oil	lb.	.20 —	.21
Cottonseed oil, crude	lb.	.17½ —	.18
Linseed oil, raw, cars	gal.	1.28 —	...
Peanut oil, crude	gal.	1.37 —	...
Rosin oil, first run	gal.	.35 —	...
Rosin oil, fourth run	gal.	.66 —	...
Soya bean oil, Manchuria	lb.	.18 —	.18½
Turpentine, spirits	gal.	.50 —	.51

Miscellaneous Materials

Barytes, floated, white, foreign	ton	40 00 —	50.00
Barytes, floated, white, domestic	ton	30 00 —	36.00
Beeswax, white, pure	lb.	.56 —	.64
Casein	lb.	.22 —	.30
Chalk, light, precipitated, English	lb.	—	...
Fel spar	ton	8 00 —	12.00
Fuller's earth, powdered	100 lb.	1 00 —	1.50
Ozokerite, crude, brown	lb.	.65 —	.75
Ozokerite, American, refined, white	lb.	.75 —	1 00
Red lead, dry, carlots	lb.	.10 —	.11¼
Rosin, 280 lb	bbl.	6 95 —	...
Soapstone	ton	10 00 —	12 50
Talc, American, white	ton	15 00 —	22 00
White lead, dry	lb.	.09 —	.10

Refractories, Etc.

(F.O.B. Works)

Chrome brick	net ton	Nominal	
Chrome cement, Grecian	net ton	Nominal	
Clay brick, 1st quality fireclay	per 1000	50.00 —	55.00
Clay brick, second quality	per 1000	35.00 —	40.00
Magnesite, raw	ton	30.00 —	35.00
Magnesite, calcined	net ton	85.00 —	90.00
Magnesite, Grecian, dead burned	net ton	135 00 —	140 00
Magnesia brick, Grecian, 9x4½x2½	per 1000	50 00 —	60 00
Silica brick			

Ferroalloys

Ferrocarbontitanium, 15-18 per cent, carlots, f.o.b. Niagara Falls, N. Y.	ton	160.00 —	...
Ferrochromium, per lb. of Cr	lb.	.50 —	...
Ferromanganese, domestic	ton	250.00 —	...
Ferromanganese, English	ton	325.00 —	...
Ferromolybdenum, per lb. of Mo	lb.	3 00 —	...
Ferrosilicon, 75 per cent, f.o.b. N. Y.	ton	—	
Ferrosilicon, 50 per cent, carlots, del., Pittsburgh	ton	165.00 —	175.00
Ferrosilicon, 50 per cent, contract	ton	100.00 —	175.00
Ferrotungsten, 75-85 per cent, f.o.b. Pittsburgh	lb.	2 35 —	2 45
Ferrouranium, f.o.b. works, per lb. of U	lb.	7 00 —	...
Ferrovanadium, f.o.b. works	lb.	3.50 —	4 50

Ores and Semi-finished Products

Antimony ore, per unit		1 60 —	1 75
Chrome ore, 48 per cent minimum, f.o.b. Cal., per unit	ton	1.50 —	...
Manganese ore, 48 per cent and over, per unit	ton	1 20 —	...
Manganese ore, chemical	ton	80 00 —	100 00
Molybdenite, per lb. of MoS_2	lb.	2 15 —	2 20
Tungsten, Scheelite, per unit of WO	ton	24 50 —	...
Tungsten, Wolframite, per unit of WO	ton	24 50 —	...
Uranium oxide, 96%	lb.	3 25 —	3 60
Vanadium pentoxide, 99%	lb.	10.50 —	...
Pyrites, foreign	unit	16 —	16½
Pyrites, domestic	unit	25 —	30

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

ALVORD & FRENSDORF, INC., Syracuse, N. Y. Capital, $200,000. To engage in the manufacture of fertilizer, glue, etc. Incorporators: S. and C. B. Frensdorf, and J. Buff, 112 Warner Street, Syracuse.

THE ATLAS PRODUCTS COMPANY, Chicago, Ill. Capital, $25,000. To engage in a general potash production business. Incorporators: B. Prentiss, P. Zak, and B. F. Cowan, Chicago.

BAMBERGER & ROBBINS, INC., Wilmington, Del. Capital, $50,000. To manufacture paints, varnishes, etc. Incorporators: James McClafferty, James P. Robbins and Samuel Waity, Wilmington.

THE BARNES CHEMICAL WORKS, Paterson, N. J. Capital, $250,000. To manufacture chemicals and allied products. Incorporators: John W., H. J., and L. E. Laffey, Paterson.

THE BERGOM PRODUCTS COMPANY, New York. Capital, $10,000. To manufacture chemicals, dyestuffs, and kindred products. Incorporators: J. M. Barry, A. C. Thiel and J. L. Fox, 571 West One Hundred and Fifty-ninth Street.

THE BIG SHOT LEAD & ZINC COMPANY, Ardmore, Okla. Capital, $50,000. To mine for lead and zinc. Incorporators: B. S. Curtis, A. T. West, and D. K. Pope, Ardmore.

THE BINDER PAPER BOX COMPANY, Newark, N. J. Capital, $25,000. To manufacture paper boxes, etc. Incorporators: E. Herman, Harry Levin, and K. Fitzgerald, Newark.

THE BLAST FURNACE PRODUCTS CORPORATION, Dover, Del. Capital, $1,000,000. To manufacture apparatus for blast furnaces, etc. Incorporators: Joseph Mann, Bloomfield, N. J.; Arthur P. McKinstry, New York; and Erwin B. Hallett, Brooklyn, N. Y.

THE CALDWELL GLASS COMPANY, Pittsburgh, Pa. Capital, $25,000. To manufacture glassware of various kinds. H. P. Fitzpatrick is the principal incorporator.

THE CENTURY MINING COMPANY, Miami, Okla. Capital, $300,000. To engage in a general lead and zinc business. Incorporators: L. B. Parker and George Weems, Miami, and G. H. Ennis, Mounds, Okla.

THE CONNORS STEEL COMPANY, Birmingham, Ala. Capital, $300,000. To construct and operate a rolling mill for the manufacture of steel hoops, bars, bands, channels, and other steel products. Incorporators: George W. Connors, W. M. Hoke, and S. S. Paul.

THE COMMERCIAL STEEL CASTINGS COMPANY, Marion, Ohio. Capital, $150,000. To manufacture open-hearth steel castings. Incorporators: J. D. Owen, C. A. Owen, D. W. Evans, George D. Copeland, M. C. McNeil, R. H. Beidenbaugh, and H. J. Barnhart.

THE COOSA CARBON COMPANY, Birmingham, Ala. Capital, $150,000. To engage in the development of graphite properties. Incorporators: H. W. Blake, W. A. Neal, P. McGeever, and Robert T. Epperson.

THE CHARLES E. DAVIS FOUNDRY COMPANY, INC., Rutland, Vt. Capital, $75,000. To operate a local foundry. Incorporators: Charles E. Davis, M. I. Mullin, and J. N. Page, Rutland.

JAMES H. DEDERICKS' SONS, INC., Jersey City, N. J. Capital, $30,000. To smelt, refine and deal in gold, silver and other metals. Incorporators: C. A. Cole, Arthur R. Oakley, Paul E. Birtsch, Jersey City.

EDINBURG PAINT & MANUFACTURING COMPANY, Edinburg, Va. Capital, $200,000. To manufacture paints, varnishes, etc.

THE FEDERAL PAPER CAN & CARTON COMPANY, New York. Capital, $10,000. To manufacture paper boxes and other paper specialties. Incorporators: C. C. Wippman, L. S. Lockhart, and E. C. Cushman, 51 Chambers Street.

THE FLORIDA GLASS COMPANY, Tampa, Fla. Capital, $250,000. To manufacture glass and glassware of various kinds. Incorporators: C. J. Earley, Paul T. Davis, and L. M. Stahl, Tampa.

THE GASOLINE ECONOMY COMPANY, Dover, Del. Capital $100,000. To manufacture devices for the use of oil and products thereof.

THE GOLDEN SPIKE MINING COMPANY, Oklahoma City, Okla. Capital, $125,000. To mine for lead and zinc. Incorporators: R. H. Drenna, F. E. Herrin, and O. D. Halsell.

THE HENDERSON PLANTATION COMPANY, Memphis, Tenn. Capital, $500,000. To operate cotton gins, cotton seed oil mills, etc. Incorporators: Frank Hayden, L. K. Salsbury, and J. S. Sbortle, Memphis.

THE HOFFMAN PERRY IRON & STEEL COMPANY, Youngstown, Ohio. Capital, $75,000. To operate a plant for the manufacture of iron and steel products. Incorporators: L. J., and Frank C. Hoffman, Youngstown.

THE HUGO BRAND LEATHER COMPANY, New York. Capital, $25,000. To manufacture leather and leather specialties. Incorporators: L. R. Benjamin, E. B., and H. Brand, 622 West One Hundred and Thirteenth Street, New York.

THE IRON CITY FOUNDRY COMPANY, Hamilton, Ohio. Capital, $50,000. To operate a large plant. Incorporators: Albert D. Stuckey and C. E. Freeman.

THE C. E. ISING CORPORATION, New York. Capital, $100,000. To manufacture chemicals and allied products. Incorporators: C. T. Johnson, Youngstown, O., and F. Baer, 550 West One Hundred and Seventy-eighth Street, New York.

THE JOPLIN-MIAMI LEAD & ZINC COMPANY, Oklahoma City, Okla. Capital, $100,000. To engage in a general mining business for the production of lead, zinc, etc. Incorporators: E. M. Butler, R. E. Burks, Oklahoma City, and E. Carman, Springfield, Mo.

THE KINGSPORT WOOD REDUCTION COMPANY, Chicago, Ill. Capital, $2,000,000. To reduce, distill, and treat wood. Incorporators: Harry H. Phillips Charles J. Horn, and Burrell J. Cramer, Chicago.

THE KETOL COMPANY, Newark, N. J. Capital, $50,000. To engage in the production of coal and wood tars. Incorporators: Charles S. Coe, East Orange; John H. Yocum, Newark, and Lewis M. DeForge, South Orange.

THE LA NORA MINING COMPANY, Chitwood, Mo. Capital, $48,000. To mine for lead and zinc. Incorporators: George G. Bayless, Carterville; Phil Gray, Webb City, Mo.

THE F. G. LASHER COMPANY, Brooklyn, N. Y. Capital, $75,000. To manufacture chemicals, dyestuffs, etc. Incorporators: F. W. Parker, D. Dosher, and F. G. Lasher, 104 Grove Street, Brooklyn.

THE EDGAR LEVINSTEIN COMPANY, Boston, Mass. Capital, $250,000. To manufacture chemicals and allied products. Incorporators: Harry R. Davies, Edgar Levinstein, and George L. Bishop, Boston.

THE LOCKPORT LEAD MINING COMPANY, Owenton, Ky. Capital, $30,000. To mine for lead, etc. Incorporators: J. T. Walker, H. C. Green, Sr., N. E. Foster, and F. H. Brown, Owenton.

THE LOOKOUT PAINT COMPANY, Chattanooga, Tenn. Capital, $100,000. To manufacture paints, varnishes, etc. J. H. Stewart is the principal incorporator.

THE LUCKY PAT MINING COMPANY, Miami, Okla. Capital, $150,000. To mine for lead, zinc, etc. Incorporators: L. C. Kropp, Vinita, Okla.; O. O. Snyder, and S. H. Mates, Pryor, Okla.

THE MENDLESON CORPORATION, Albany, N. Y. Capital, $2,000,000. To manufacture potash, chemicals, lime, etc. Incorporators: I. Mendleson, J. and L. Mendleson, 644-A Madison Avenue, Albany.

THE METALS & CHEMICAL CORPORATION, Dover, Del. Capital, $100,000. To manufacture chemicals, colors, dyes, etc.

THE MIAMI ZINC & LEAD COMPANY, Portland, Me. Capital, $3,000,000. To mine for zinc and lead. Incorporators: E. V. Mann, E. H. Irwin, and C. D. Booth.

THE MO-VA-CU PRODUCTS CORPORATION, New York. To manufacture chemicals, oils, etc. Incorporators: C. A. Rucker, Jr., J. J. Haesler, and W. A. White, 229 West One Hundred and Ninth Street, New York.

THE NATIONAL STEEL BARREL COMPANY, Cleveland, Ohio. Capital, $200,000. To manufacture steel products. Incorporators: P. R. Long, C. F. Schriner, John A. Nally, and J. J. Schriner.

THE NORTH CAROLINA TIN COMPANY, Cherryville, N. C. Capital, $100,000. To manufacture tin. Incorporators: M. S. Mauney, D. A. Rudisill, and N. A. Stroup.

THE NATURAL CHEMICAL PRODUCT COMPANY, Lexington, N. C. Capital, $350,000. To manufacture chemicals and allied products, mainly potash from feldspar. Incorporators: C. Berg, of New York, president-chemist; G. W. Mountcastle, vice-president; W. L. Crawford, secretary-treasurer, both of Lexington.

THE PITTSBURGH THERMOLINE COMPANY, Pittsburgh, Pa. Capital, $100,000. To manufacture compressed liquid gas for the welding of iron and other metals. Incorporators: John P., Harry O., and Walter E. Eichleay, Pittsburgh.

THE RAINBOW MINING & DEVELOPMENT COMPANY, Miami, Okla. Capital, $25,000. To engage in a general mining business. Incorporators: F. E. Atchlet, W. A. Spurlin, and R. M. Radcliffe, all of Erick, Okla.

THE RED-OINT-A CHEMICAL COMPANY, Portland, Me. Capital, $10,000. To manufacture chemicals, etc. Incorporators: A. M. Brown, Winchester, Mass.; W. D. Hobson, Portland.

THE SHARTEL MINING COMPANY, Oklahoma City, Okla. Capital, $25,000. To mine for lead and zinc. Incorporators: Charles Hoopes, J. W. Shartel, and W. C. Jones, Oklahoma City.

THE SHUTTLEWORTH-WOLLNY COMPANY, New York. Capital, $10,000. To manufacture paper, paper boxes, etc. Incorporators: C. J. Wollny, F. Keiller, and W. E. Shuttleworth, 474 West Broadway, New York.

DAVID H. SMITH & SONS, INC., Brooklyn, N. Y. Capital, $100,000. To manufacture iron and steel products. Incorporators: D. H. Smith, Mahwah, N. J.; M. F. Smith, Brooklyn, N. Y.; and J. C. Snyder, 256 Broadway, New York.

THE STAMBAUGH IRON COMPANY, Cleveland, Ohio. Capital, $10,000. To operate a local iron works. Incorporators: F. McKenzie and F. J. Moriarity.

Construction and Operation

Alabama

BESSEMER.—The National Steel Products Company has recently acquired a large piece of property and is planning for the immediate construction of a new plant. It is expected to have the works completed and ready for operation within three months.

Arizona

VERDE.—The United Verde Extension Mining Company is having plans prepared for all buildings required for the new townsite at its local smelter. Sewer, water, and electric lighting system will also be installed, the entire work being estimated to cost approximately $2,000,000.

RAY.—The Ray-Hercules Copper Company is rushing to completion the erection of its new initial mill unit, and is planning to inaugurate operations at an early date. When completed, the first unit of the plant will have a capacity of 1,500 tons of ore daily.

Arkansas

NORTH LITTLE ROCK.—Fire recently destroyed a large portion of the Buckeye Cotton Oil Mill of the Procter & Gamble Soap Company, Cincinnati, Ohio, with loss said to be approximately $400,000. It is reported that the works will be immediately rebuilt. A. B. Carr is manager.

LITTLE ROCK.—The Arkansas Foundry Company has acquired property at the foot of East Sixth Street, and is planning for the establishment of a new foundry for the production of gray iron castings for railroad construction, to have a capacity of about 15 tons daily.

YELLVILLE.—The Deep Mining Company, recently organized, is plannnig for the early development of deep ore bodies on Cowan Barrens, between Yellville and the Rush mining camp on Buffalo River.

California

MARTINEZ.—The Atlas Powder Company is said to be planning for the construction of a large addition to its Giant Powder plant. The company has recently acquired a site consisting of about 200 acres of land adjoining the works.

SAN DIEGO.—The United States Government, Navy Department, has awarded a contract to John W. Danforth Company, 70 Ellicott Square, Buffalo, N. Y., for the

construction of a new local concrete and steel fuel oil plant, to cost about $275,000.

OAKLAND.—The Judson Manufacturing Company is making rapid progress in the construction of a new addition to its rolling mill at the foot of Park Avenue.

OAKLAND.—The Spencer-Kellog Company, Edgewater, N. J., is planning for the construction of a new linseed oil plant on a local site now under consideration. The works, which will be among the largest in the world, are estimated to cost $400,000.

SAN FRANCISCO.—The Pacific Gas & Electric Company is planning for extensive improvements and additions to its plant at Fresno. A portion of the work, which will cost about $400,000, has been commenced.

SAN FRANCISCO.—Announcement has been made that effective January 1, 1918, the Pacific Hardware & Steel Company and Baker & Hamilton will be merged into one corporation, to be known as the Baker, Hamilton & Pacific Company, capitalized at $4,250,000. Alexander Hamilton is president of the new company.

FILLMORE.—The Ventura Refining Company has completed the construction of its new local wax refinery, and operations have been inaugurated. The product of the new plant is in great demand for the making of explosives, paper boxes, etc.

KESWICK—The Mountain Copper Company is having plans prepared for the construction of a new addition to its oil flotation plant for the treatment of copper ore at the Minnesota station, between Keswick and Iron Mountain, to double the present capacity. When completed, the works will have an output of about 1,040 tons daily.

Colorado

CRIPPLE CREEK—The Vindicator Consolidated Gold Mining Company has completed improvements in its 600-ton flotation mill. At the present time the mill produces about 12 tons of concentrate daily, running from $25 to $30 per ton.

Connecticut

ANSONIA.—The American Brass Company has taken out a building permit for alterations and improvements in a two-story building, about 30 x 100 ft., now used for storage purposes, to provide for increased capacity.

NEWINGTON.—Construction is being rushed to completion on the new two-story paper mill being erected for Thomas F. Garvan. The structure is about 47 x 147 feet, and the installation of the necessary equipment has been commenced.

STAMFORD.—The American Synthetic Colors Company is planning for the construction of a large addition to its plant to provide for increased capacity. The structure is estimated to cost $30,000.

WATERBURY.—The Connecticut Brass & Manufacturing Company, which recently took over the Tilling Brass Company, is planning for the erection of a one-story addition to its plant to provide for increased capacity.

Delaware

NEWARK.—The plant of the Jacob Thomas Company, manufacturer of wall paper, was completely destroyed by fire on Jan. 11, with loss estimated at about $225,000. The destruction of the plant has thrown about 150 hands out of employment

Georgia

CAMILLA.—The W. F. Cullens Fertilizer Company is planning for the erection of a large new addition to its plant, to provide for increased capacity.

Illinois

CHICAGO.—The Standard Steel Car Company has had plans prepared for the construction of a new one-story machine shop at its Hammond, Ind., works. The structure, which will be about 250 x 800 feet, is estimated to cost $200,000.

CHICAGO.—Rapid progress is being made by the William Glader Machine Works, North Ann Street, in the construction of a new three-story plant. The structure will be about 50 x 100 feet and cost $20,000.

Indiana

LOGANSPORT.—Fire, on January 8, destroyed a portion of the plant of the Logansport Casting Company, a section of the Western Motor Works, with entire loss estimated at $70,000. A. W. Pattu is manager.

MUNCIE.—The Eagle Foundry Company has filed plans for the construction of a new one-story addition, about 25 x 125 ft., on Willard Street. Contract has been awarded.

MUNCIE.—Fire on January 10 destroyed a portion of the plant of the Central Indiana Gas Company, Brotherton Street and Big Four Railroad, with loss estimated at $15,000. It is said the company will immediately rebuild.

Iowa

BURLINGTON.—The North Western Stamping Company has had plans prepared for the construction of a new one-story factory, about 100 x 300 feet, at its plant. A. J. Klein, Burlington, is the architect

Louisiana

BOGALUSA.—Operations have been inaugurated in the new plant of the Bogalusa Paper Company, just completed, at a cost of $1,500,000. The plant will be operated largely on waste from the works of the Great Southern Lumber Company, situated near here.

SHREWSBURY.—The Planters' Fertilizer & Chemical Company, controlled by Armour & Company, Chicago, Ill., has just completed the erection of a large plant for the manufacture of boneblack. This is the first plant of its kind in the South, and the output, which is most universally used in the refining of sugar, will be utilized almost exclusively in this State.

BREAUX BRIDGE.—The Southern States Oil & Gas Company, Indianapolis, Ind., has acquired property on Banard Street, about 500 x 1000 ft., and is planning for the erection of a large new oil refinery. This location gives the company both water and rail facilities for transportation.

NEW ORLEANS.—The United Chemical & Organic Products Company, which recently acquired the local plant of the Hirsch-Stein Company of Chicago, has completed all building units in accordance with its original plans. The company will specialize in the production of commercial chemicals and by-me products. An investment of approximately $500,000 is represented in the new construction, etc.

Maryland

BALTIMORE.—The Piedmont-Mt. Airy Guano Company has filed plans for the construction of a new fertilizer building to cost about $60,000. Contract for erection has been awarded.

BALTIMORE.—Fire recently destroyed a portion of the plant of the American Propeller Works, Light Street, with loss estimated at approximately $90,000. The company is considering plans for the immediate reconstruction of the destroyed section.

CURTIS BAY.—The Industrial Alcohol Company has awarded a contract to the Austin Company, Bulletin Building, Philadelphia, Pa., for the construction of three new two-story manufacturing buildings to cost about $100,000.

SPARROWS POINT.—The Bethlehem Steel Company will build new one-story addition to its plant, about 30 x 35 ft., and 35 x 60 ft.

Massachusetts

EVERETT.—The New England Oil, Paint & Varnish Company is making rapid progress in the construction of its new one-story factory addition, about 30 x 48 ft. The company is planning to complete the structure and commence the installation of machinery at an early date

EAST CAMBRIDGE.—Fire recently destroyed the local car-building and repair shops of the Boston & Maine Railroad, including damages to the power house, roundhouse, machine shop and blacksmithing works. The entire loss is estimated to be approximately $150,000. It is said that the rebuilding will be commenced at once

LOWELL.—The International Steel Company, Middlesex Street, has taken out a building permit for the construction of a new addition, about 20 x 100 feet, to its plant

MARLBORO.—The Lapointe Machine Tool Company, Tower Street, is making rapid progress in the construction of a large new addition to its plant, to provide for increased capacity.

SPRINGFIELD.—The Springfield Aircraft Corporation has commenced the construction of a new addition to its plant to cost $50,000. Wyckoff & Lloyd, Springfield are the contractors.

SPRINGFIELD.—The Fleming Foundry Company has filed plans for the construction of a new two-story addition, about 50 x 55 feet, to its foundry. Contract has been awarded to the W. A. Newton Company, Springfield.

WORCESTER.—The Worcester Glass Company has commenced operation in its new plant on May Street, to be devoted to the manufacture of French mirrors, bevel plates, automobile shields, etc.

Michigan

JACKSON.—Fire completely destroyed the plant of the Perlman Rim Company, manufacturer of automobile rims, etc., recently, with loss estimated at approximately $80,000.

Minnesota

MINNEAPOLIS.—Fire recently completely destroyed the large plant of the Kansel Foundry Company, Dartmouth Street and Twenty-seventh Avenue, S. E. It is said the works will be rebuilt at once. John Kansel heads the company.

Missouri

KANSAS CITY.—The Sinclair Refining Company, Tulsa, Okla., has completed all plans for the construction of its new oil distributing station at Harrison Street and the Kansas City Railway Terminal. The new plant will comprise a large oil filling station, pump house, boiler room and locker room, one-story repair plant and garage, three-story and basement, barrel house, and administration building. The Leonard Engineering Company, McCormick Building, Chicago, Ill., is engineer and contractor.

ST. LOUIS.—The St. Louis Malleable Casting Company, Conduit Avenue, has completed all plans for the construction of a new plant to comprise a forge shop, machine shop, foundry, electric power plant, and auxiliary structures. The entire works, when completed, are estimated to cost about $100,000.

Montana

BAKER.—The Treasure State Gas & Oil Company, which was recently taken over by New York interests, is planning for the immediate installation of a large carbon plant on Cabin Creek, about twenty miles north of Baker. The company will also sink three more wells within the next few months for the purpose of procuring sufficient gas to supply the requirements of the carbon plant.

Nebraska

OMAHA.—The laboratory and administration building of the American Smelting & Refining Company was recently destroyed by fire, with loss estimated at approximately $25,000.

New Jersey

DOVER.—One of the comparatively new and permanent industries to be established and located in the Dover manufacturing district is the International High Speed Steel Company. Their plant is located along the Delaware, Lackawanna & Western Railroad, about two miles from the center of Dover. They manufacture hollow and solid rock drill steel, which is used chiefly for mining purposes. Before the declaration of war in Europe, hollow rock drill steel was not made in the United States, and at the present time the International High Speed Steel Company is the only concern in the United States that manufactures hollow steel. They now have orders sufficient to keep their plant in operation at capacity for the next two years. None of these orders are war orders. All current for power, lighting and electric furnaces is supplied by the New Jersey Power & Light Co.

EDGEWATER.—Spencer Kellog & Sons have filed plans for the construction of a new five-story addition to their oil manufacturing plant, about 30 x 50 feet. Contract for construction has been awarded to the John W. Ferguson Company, 152 Market Street, Paterson.

BLOOMFIELD.—Organization papers have been filed by the Mayland Manufacturing Company, notifying of intent to operate a chemical manufacturing works at 71 Willett Street. Anthony J. Mayland heads the company

BOUND BROOK.—For the purpose of increasing its capacity, and for the completion of a large Government order, the Cyclo Chemical Company, Bound Brook Road, manufacturer of chemicals, has commenced the construction of a large new addition to its plant. Frank N. Goble, 1 East Forty-second Street, New York, has the contract for erection.

HOBOKEN.—Fire recently destroyed the plant of the Gatti-McQuade Company, manufacturer of mill supplies and paper, with loss estimated at approximately $250,000.

JERSEY CITY.—The Humphrey Mantle Company, formerly located at Gloucester, has acquired a four-story factory building at 61-67 Bishop Street, and is planning to install equipment at once for the manufacture of gas mantles.

HARRISON.—The National Oil Products Company, Essex Street, is planning to greatly increase the capacity of its local plant, and has commenced the construction of several new additions for this purpose.

NEWARK.—The Butterworth-Judson Corporation, Avenue R, manufacturer of chemicals, has taken out a building permit for the construction of a new two-story addition to its plant, about 60 x 105 ft. The structure will cost $12,000.

NEWARK.—A new one-story brick condenser house addition, about 40 x 60 ft., will be erected at the chemical manufacturing plant of the Maas & Waldstein Company, Avenue R. The company has taken out a building permit for the structure.

KINGSLAND.—The Nitro Chemical Corporation, 20 Broad Street, New York, has recently acquired a portion of the local plant of the Canadian Car & Foundry Company, and is planning to commence immediate construction of about twenty-five new buildings, 60 x 400 ft., to be devoted to the manufacture of picric acid for the Government. When running to capacity, it is expected that the plant will have an output of approximately 800,000 pounds monthly of wet picric acid, which is used in the manufacture of hand grenades. About 4000 hands will be employed. Contract for the construction of the new plant has been awarded to W. J. Burke, Lyndhurst.

PERTH AMBOY.—Fire, on Jan. 12, destroyed a portion of the plant of the Roessler & Hasslacher Chemical Company, with loss estimated at about $25,000. The company has recently conveyed to the General Bakelite Company, manufacturer of insulation specialties, a subsidiary organization, property at Fayette and Rector Streets. It is said that the site will be used for extensions to the latter company's plant.

TRENTON.—The Globe Rubber Tire Company is planning for the construction of additions and improvements at its plant to provide for increased capacity.

New York

NEW YORK.—The Andes Exploration & Smelting Corporation, 68 William Street, has filed notice of a change in its corporate name to the Andes Electric Corporation.

BROOKLYN.—Lehn & Fink, 39 Sedgwick Street, manufacturers of chemical compounds, etc., have had plans prepared for the construction of a new addition to its brick plant to cost about $60,000. Buchman & Kahn, 30 East Forty-second Street, are the architects.

BROOKLYN.—The Continental Varnish Company, Newark, N. J., has awarded a contract for the erection of its proposed new factory group to be located at Ingraham Street and Varick Avenue. The new works will include a one-story main building, 60 x 80 ft., varnish house and garage, mixer building, and auxiliary structures, the entire work to cost $25,000. The Amsel Construction Company, 927 Broadway, Brooklyn, is the contractor.

FARMINGDALE, L. I.—The Farmingdale Chemical Company, manufacturer of chemicals and allied products, has acquired the plant of the E. C. Nelson Manufacturing Company, Farmingdale, for a consideration of about $75,000, and is planning to operate the works for the manufacture of chemicals which were obtained from Germany before the war.

LONG ISLAND CITY.—The Akron Tire Company, Honeywell Street and Skillman Avenue, has had plans prepared for the construction of a new one-story brick addition, about 50 x 95 ft., to its plant. The structure will cost $12,000.

LONG ISLAND CITY.—The Van Iderstine Company, Railroad Avenue, manufacturer of soaps, etc., is planning for the immediate construction of a new six-story reinforced-concrete plant, about 90 x 120 ft., on Newtown Creek, to cost about $70,000.. Plans have been prepared.

LONG ISLAND CITY.—The Pittsburgh Plate Glass Company is planning for the erection of a large new plant, about 260 x 280 ft., to be located on Hunters Point Avenue. The works are estimated to cost $350,000. and plans are now in course of preparation.

LITTLE FALLS.—Fire recently damaged the plant of the Barnet Leather Company, East Mills Street, manufacturer of leather. The destroyed section will be immediately rebuilt.

JAMESTOWN.—The Curtis Machine Company, East Second Street, which was engaged in the manufacture of propellers for aeroplanes for the Government, was partially destroyed by fire recently, with loss estimated at $35,000.

BALLSTON SPA.—Fire recently destroyed a portion of the plant of the American Hide & Leather Company, which is engaged on United States Army contracts, with loss estimated at $35,000. The tannery will be immediately rebuilt.

North Carolina

ASHEVILLE.—Anson G. Betts & Company, operating a mine at Shut-in-Creek for the production of iron ore, has greatly increased its output since the entrance of the United States in the war, and is planning for further development work.

CHARLOTTE.—Fire recently destroyed the local plant of the Buckeye Cotton Oil Company, with loss estimated at $100,000. The main plant of the company, which is located on the outskirts of the city, was not damaged.

Ohio

CANTON.—The ten new steel mills constructed as an addition to the plant of the Berger Manufacturing Company at a cost of approximately $4,000,000 will be completed at an early date, and the company is planning to inaugurate operations. The new additions will increase the output of the plant from 100,000 tons a year to about 160,000 tons.

CASTALIA.—The Castalia Cement Company is seriously considering the construction of a large local plant to be devoted to the production of potash as a byproduct.

COLUMBUS.—Fire, on January 9, destroyed the local plant of the American Chain Company. The loss is estimated at $150,000. The plant was engaged in the manufacture of chains for the Government, and about 800 employes are thrown out of work.

MARION.—The Commercial Steel Castings Company, recently incorporated with a capital of $150,000 is planning for the immediate construction of a large plant to have a capacity of about 20 tons of finished castings daily. The new works will give employment to about 125 hands for initial operations.

YOUNGSTOWN.—The Liberty Steel Company, which is now constructing an eight-mill tinplate plant near Warren, is planning for the construction of four additional mills, making it a twelve-mill plant. The works were originally planned for the production of steel sheets, but the procedure was changed when the heavy demand for tin became apparent.

YOUNGSTOWN.—The Carnegie Steel Company has inaugurated operations at its new bar mill just completed. Three other mills are also in course of construction.

Oklahoma

OIL CITY.—The American Industrial Oil Company, Oklahoma City, has acquired the Kenthoma property consisting of about 90 acres, and is planning for the immediate construction of a new refinery. The company has awarded a contract to B. Stutsel, Oil City, for the drilling of thirty-five additional wells.

Pennsylvania

BRADFORD.—S. A. Mundy and associates have organized a new company with a capital of $3,500,000, and are planning for the erection of a large pulp mill to cost about $1,000,000 in southern Ontario. It is said the mill will provide employment for approximately 200 returned Canadian soldiers.

JOHNSTOWN.—Fire recently destroyed the benzol manufacturing plant of the Cambria Steel Company, with loss estimated at $30,000. The company will commence the rebuilding of the works at once.

NEWPORT.—The American Manganese Company is planning for improvements in its plant. Contract has been awarded for the relining of its local stack.

PHILADELPHIA.—The Thomas Potter Sons & Company, Second and Erie Avenues, manufacturers of linoleum, have had plans prepared for alterations in their plant.

PITTSBURGH.—The hammer shop and 21-inch mill at the Park plant of the Crucible Steel Company, Thirty-first and Smallman Streets, was destroyed by fire recently with loss estimated at about $30,000. The company will immediately rebuild.

SCRANTON.—The American Color Company, Coal Exchange Building, has taken bids for the construction of a new addition to its plant at Penn Avenue and Carbon Street, to cost $40,000.

TIONESTA.—Fire, due to an explosion, recently destroyed the plant of the Interior Oil & Gas Company, with loss estimated at $15,000.

South Carolina

FLORENCE.—The main seed house of the Southern Cotton Oil Company's plant, including machinery, equipment and 700 tons of cotton seed, was destroyed by fire recently, with loss estimated at $70,000.

Tennessee

HADLEY'S BEND.—The United States Government, War Department, is planning for the construction of a large new manufacturing plant to be devoted to the production of explosives at Hadley's Bend, near Nashville. When running to capacity, the plant is estimated to give employment to about 15,000 hands. The project will require an investment of approximately $60,000,000. Contract for construction has been awarded to the Thompson-Starrett Company, New York.

BON AIR.—The Bon Air Coal & Iron Corporation is progressing very rapidly with its development plans, and has just opened two new mines at Eastland and Bon Air. The company is planning to increase the output to about 2,000 tons daily. The coke ovens at Eastland are now being prepared for the manufacture of furnace coke to be supplied to the Allens Creek iron furnace. This company was recently organized with a capital of $10,000,000.

Texas

DALLAS.—The Texas Steel Company, which recently acquired the Rusk foundry property at Rusk, is planning to inaugurate operations at the plant within the next three months for the manufacture of pig iron and iron pipe. The company is also considering the erection of a large steel plant of 700 tons daily capacity at Beaumont.

ORLA.—The Standard Sulphur Company, Detroit, Mich., has acquired property near Orla on the Santa Fe Railway, and is planning for the construction of the initial unit of its plant, to have a capacity of 100 tons of refined sulphur daily. Estimated cost of the project is $75,000.

Utah

GUNNISON.—The Gunnison Valley Sugar Company is making rapid progress in the construction of its large new plant, and it is expected that the works will be completed early in the spring. The cost of the new factory is said to be $500,000.

SALT LAKE CITY.—The Utah-Idaho Sugar Company, Vermont Building, has acquired property, about 93 acres, near Sunnyside, as a site for the construction of a large new sugar factory.

Virginia

HUNTINGTON.—The Virginian Potteries Company, recently organized, is planning for the construction of a new plant for the manufacture of pottery. The first unit of the works will be about 150 x 500 ft. W. H. Dunn is manager.

West Virginia

CLARKESBURG.—Fire recently destroyed a portion of the plant of the Norwood Glass Company, with loss estimated at $75,000, throwing about 300 hands out of employment. It is said that the plant will be immediately rebuilt. E. Hockstrosser is general manager.

CHARLESTON.—The United States Government has purchased about 1500 acres of land near Charleston, and is planning for the construction of a large plant for the manufacture of explosives, powder, etc., at a cost of $9,000,000.

Washington

LA GRANDE.—The American Nitrogen Products Company is planning for the installation of three new electric ovens, to provide for increased capacity. Contract has been awarded to the National Engineering & Equipment Company, L. C. Smith Building, Seattle.

Wisconsin

MENASHA.—The plant of the Wisconsin Rendering Company was recently destroyed by fire, with loss estimated at $10,000. The destroyed section will be rebuilt, it is said.

A Legislative Solution of the Niagara Problem

FROM a bill introduced in the Senate of the State of New York by Mr. Gibbs on Jan. 15, 1918, we extract the following:

> "The sum of three million dollars ($3,000,000), or so much thereof as may be necessary, is hereby appropriated, payable out of the moneys realized under the sale of bonds as provided by section one of this act, to be expended by the commissioners of the state reservation at Niagara for the preparation of plans, specifications and estimates and the construction and equipment of a hydro-electric power plant, to be constructed under their supervision and control on land belonging to the state on the state reservation at Niagara, which plant when completed and equipped shall develop not less than five hundred thousand horsepower."

This indicates a capital cost of not more than $6 per horsepower developed! An engineer might doubt his ability to do so much within the limits of the appropriation; but provision is made, with great foresight, for the limitations of mere engineering ability:

> "The legislature shall prescribe the method and manner by which such commissioners shall obtain the necessary plans and specifications and estimates and prescribe their powers and duties in connection with the construction and operation of such plant."

An excellent example of the Bolshevik principle that any feat can be achieved by legislative action.

Meanwhile some Senator might with advantage introduce the following amendment:

> "The sum of thirty cents (30c.), or so much thereof as may be necessary, is hereby appropriated, to be expended for the elementary education of Mr. Gibbs in the subject of the cost of hydro-electric development."

The War Department Discovers the Chemist

FROM the time the United States entered the war to the present day there have been a few people who realized the importance of the chemist in the general scheme of industrial affairs. And when it was proposed to take him from his tasks and make a soldier of him, there were a few voices raised in opposition.

Comes now the Adjutant General of the Army, however, with official recognition of the importance of the chemist in industry. Through an order of the Adjutant General provision has been made whereby manufacturers of essential war materials who have lost chemists through the first draft may again obtain the services of these men, and those now threatened with the loss of chemists through the present draft may retain them. The request for exemption must come from the manufacturers; applications from the men will not be considered. Manufacturers thus affected should apply to the Chemical Service Section, N. A., New Interior Building, Washington, D. C., for the regulations governing the transfer of men already drafted or the possible reclassification of men not yet called.

The Need of Co-ordination at Washington

CONSIDER the United States as being in business, for war is business on so vast a scale as to transcend any other enterprise with which it might be compared. The particular feature of this business is production; munitions and supplies must be made and taken to armies in the field. It has been said that this is a war of production and transportation. Another feature of this business is that it is incidental to our political life and is not the normal pursuit of our political officers. Being incidental, it is conceivable that it may not be run efficiently by men selected for reasons wholly foreign to the making of war, and consequently unfamiliar with its *modus operandi*. A logical antidote for this inevitable inefficiency is to model the nation's business of the moment along the lines of private industry.

Now private industry has been the subject of searching analysis in recent years, with the result that problems of production have been pretty well solved and standardized. The production engineer has been having his innings in business, and he has made some effective hits. One of the conditions which he regards as fundamental in a manufacturing business is complete co-ordination of the work of the several departments that contribute to the finished product. The principle is axiomatic. It were unwise for an automobile maker, for instance, to allow the production of wheels, brakes, engines and bodies to proceed promiscuously, lest his unsystematic methods bring him to grief. Or, in more homely vein, he were a poor chef who would so direct the preparation of a dinner that the dessert spoiled before the soup was prepared.

In simple affairs, co-ordination may be accomplished by an orderly mind; but for complex industrial problems, production charts are resorted to by engineers in order to visualize production and enable the responsible head to co-ordinate the different branches of the work.

With this background we may now consider a fundamental trouble at Washington and prescribe the remedy. There has been a lack of co-ordination in the production program. Each officer or official responsible for a particular item has made a blind drive for production without regard to the relation of his part to the whole. Production charts are an unknown quantity in some of the offices, and there is no centralized authority responsible for the entire production program. There is no one to order a lag here or acceleration there in order to prevent congestion at some points and famine at others. Finally, production has not been co-ordinated with transportation, and the resulting jam is a matter of recent history. The fuel order, in the last analysis, was a public confession of lack of co-ordination at Washington.

The remedy lies in immediately charting the work of all the procurement divisions and co-ordinating the entire production and transportation program by the appointment of a responsible head. The charting is more important and should be done first, because charts will confound and expose an incompetent director, whereas they would be the first requisite of an able man. Failing the immediate accomplishment of these things, we will have fresh disasters to face in the course of a few months or even weeks.

Misdirecting Directors

IN HIS address before the St. Louis meeting of the American Institute of Chemical Engineers, which we print elsewhere, Mr. Frank Hemingway made some observations in regard to companies engaged in chemical industry which we think important. "I know of many companies of large size," he said, "whose boards of directors are composed wholly of financiers and business men possessing no chemical knowledge whatsoever, and in which there is no co-ordination between the directing head, the chemists and engineers or chemical engineers, the sales department and the purchasing department." This is not a surprising declaration; it is even a familiar situation in American industry, chemical or otherwise, and it is a fault of which banks and financial institutions have not yet taken adequate notice. It is a legacy of High Finance developed in the palmy days of trust flotation, and we are still suffering from it. The Board of Directors was made a kind of a show-window of corporations for stock-selling purposes. It was held that with a handsome array of money-makers on the directorate any new company would be sure to earn fat dividends. We know better, but we do not believe better, because this notion has become a tradition.

The board of directors of a manufacturing concern is charged with grave responsibilities. It bears the obligations of the welfare of the corporation, of the joint and not the separate fortunes of the stockholders, and it has to do with the relations of the corporation to industry, to its employees, to the community and to society. It is not merely a finance committee. Generally speaking, the better and more competent the whole board, the less work is there for the finance committee to do. This concept of the situation is so frequently lost sight of as to constitute a grave menace to national industry. The finance committee has to do with the disposition of earnings and with borrowing money to be spent by the corporation; but what is the use in borrowing money if you do not know how to use it? Such a board as Mr. Hemingway described does not know how to use it.

The manufacturing, selling, purchasing and research departments of an industrial concern constitute its heart. If a director of an organization is not familiar with these features and with their relations to each other, his presence as a member of the board is an act of culpable neglect. No matter how rich or successful he may be, he is useless as a director until he knows what is going on within the establishment.

Our ideas of the functions of a board of directors are so loose that offenses against industry by inadequate or defective personnel are of frequent occurrence and no heed is paid to the fact. Occasionally a swashbuckling speculator bulldozes his way into membership by means of another traditional fiction that any considerable ownership of stock entitles the holder to personal representation in the body no matter how ignorant or incompetent he may be to guide the delicate and complex mechanism of affairs that the corporation has in hand. The stigmata of such a man are likely to show in the annual report. "Unnecessary charges have been eliminated," we learn, and on investigation discover that the new director has begun to cut out deadwood, which is his favorite occupation. This consists in discharging

men who have served the company for many years and who may have needed bracing but, likely as not, were faithful and needful to the organization. Affluent traders of this type are likely to hate research as smacking of theorism, which is anathema to their souls, and by the time such a man has been mixed up in the affairs of a manufacturing concern for a year, he has cut and slashed and broken the spirits of the men who remain until the whole organization is crippled—sometimes beyond repair. Generally speaking, it is a hazardous thing to tie up to an unsuccessful man, but the successful man, ignorant of the details of an industry and whose mind is closed by vanity, is a greater danger.

American industry is in a good deal of a jumble. It needs guidance. Its difficulties are rather with theory than with finance. We do not claim that a board of directors of a manufacturing corporation should consist of department heads of the company. That would involve letting the concern run itself, while it is right and proper that the directors should be representative of the stockholders and not alone of the president. But these men are useless unless they understand the business well enough to know its actual needs. Directors should be retained by stockholders for the work they can do and for their good counsel. Their business is to conserve the welfare of the whole corporation and this requires knowledge and understanding of the business in hand as well as acumen in other affairs. They should not be selected to conserve special interests or because they have made fortunes in some entirely unrelated walk of life. It is time to take annual stockholders' meetings more seriously and to shake up the proxy committees. A sense of this need may be obtained by the comparison of the live, efficient and capable boards of a number of the great American industrial corporations with the complacent body of merchants and bankers that sit in idleness and vanity on the boards of a vast number of concerns even now engaged in the struggles of birth.

Better Work Needed

THE loss of the Tuscania with American troops aboard, of whom happily but few were lost, brings to us a fuller realization of how fortunate it is that the submarine menace has been largely reduced in the past few months. But the curtailing of destruction by submarines cannot lessen our chagrin that our shipbuilding has proceeded so slowly. While it is only ten months since our formal declaration of war, it is a full year and more since the necessity of our building ships as rapidly as possible was made clearly apparent. In retrospect we seem to have done very little indeed. Possibly it is harsh to judge us by our own expectations, but if that is to be the standard we certainly are condemned. We were to start a perfect procession of wooden boats, almost a pontoon, tandem fashion, by Oct. 1, 1917. It took us months to realize the chimerical nature of that project.

We have a hard and immeasurably important task before us, and it should do us good to think for a moment of the mistakes, the egregious blunders we have made, particularly since the chances for blundering are not all past. Like the poor, we have them with us always. The wooden ship idea was embraced because, forsooth, we had no plates! What is the condition to-day? The plate mills are unable to operate at capacity because of the breakdown in transportation, but if they were they would be able to flood the country with plates. In 1916 we produced a trifle more than 1,800,000 gross tons of sheared plates, quarter-inch and heavier. To-day we can produce very nearly twice that tonnage. If we were able to build steel ships at the rate of 500,000 deadweight tons a month, which we are very far from being able to do, we could supply all the plates required, meet all possible export demands, and still have a large surplus. Twelve months ago we were thinking of wooden ships as the only thing possible, but those easily possible, and nine months ago General Goethals' announcement that he was turning to steel ships, and had been promised the steel plates, started a controversy which it is unpleasant, but perhaps profitable, to keep in recollection.

It is difficult to correlate what we see. Everybody has a job and presumably everybody is working at it. Fuel Administrator Garfield stated in connection with his plant-closing order that production had outrun requirements, hence a little holiday could do no material harm. What is the work that is being done? The people have certainly decreased their consumption. There is very little building, except in connection with war work. Altogether, if we are really at work we should be producing more, along right lines, than we are. More production, with less consumption in ordinary peace activities, are the two material desiderata. Apparently we have them both, in very large measure, but the sum of the two items, which represents the war activity, should be large, very large, and yet it does not seem to be so.

It is clear, at any rate, that ordinary commercial activity has greatly decreased. "Business as usual" has been killed as a slogan, and very properly. Forces, ability to do things to help win the war, are released, but it does not seem that they are fully and intelligently employed.

Much regret has been expressed of late that things should come to light of a nature calculated to dampen our enthusiasm in "winning the war." That is not the philosophy of winning wars, however. As was said of discovering the North Pole, "It's dogged as does it." It is not national psychology that excitement and enthusiasm increase as war is carried on. That comes early. What wins is the dogged determination, directed by intelligence.

Two things in particular are requisite. There must be a better system at Washington as regards the placing and following up of orders, and there must be a restoration of rail transportation facilities. The reform at Washington is in progress. Matters have been brought to the light. The confusion and argument may be unpleasant, but it will bring results.

As to the railroads, our enemy was an unprecedentedly hard Winter, our ally will be Spring. Transportation conditions have been so bad, crippling sadly nearly all industries, that it has been easy to forget that before winter came, and that not so long ago, the railroads were handling a volume of traffic far in excess of anything ever before attained. Railroad facilities were inadequate, but they were doing much better than could have been expected in the circumstances. They will do still better in future. Spring will bring new life, and the epidemic of spring fever will be the lightest in a generation, thanks to Mr. Hoover!

Advantages of Hydro-Electric Power

To the Editor of Metallurgical & Chemical Engineering

SIR:—All the large industrial plants at Sault Ste. Marie are running as usual under special exemption by Dr. Garfield and W. K. Prudden from their recent and drastic fuel orders. These plants are operated by electricity produced by water power from the rapids of the St. Mary's River. The Michigan Northern Power Company and Edison Sault Electric Company produce and distribute about 40,000 hp. from these rapids. This power is used to operate all industries of any size at the Sault, including the immense plants of the Northwestern Leather Company, Union Carbide Company and Soo Woolen Mills. There is now immediately available at the Sault about 1500 hp. which can be increased to 4500 upon very short notice and the installation of the type of machinery most efficient for the operation of any particular industry.

Under the present fuel conditions this available water power is of great economic advantage to manufacturers who are or may be embarrassed for lack of fuel, the supply of which is restricted to those industries which the government may designate as essential.

We know that this item will be of interest to your readers and will naturally be pleased to have it brought to their attention.

Chemistry and the War

To the Editor of Metallurgical & Chemical Engineering

SIR:—It has been said that the present conflict is a war of chemists, and, to a very great extent, this is undoubtedly true. Never has artillery fire played so important a part in warfare.

The enormous tonnage of explosives required must by produced by the chemist. The chemist must produce also the materials for bombing and gassing, and he must furnish the fuels for ambulances, supply autos and aeroplanes. He must make the gun cotton for the war-head of the torpedo, and the high explosive for the depth bomb, the cement for concrete defenses and the gas masks for protection against the poisonous gas which the enemy chemist has produced. He manufactures many of the oils and concentrated foods used, and supplies the potash, nitrogen and phosphorus compounds used in the fertilizer necessary for the proper production of food stuffs. The khaki color which makes the soldiers' clothing inconspicuous in the field are also the product of his handiwork. He manufactures the numerous pharmaceutical products used in the hospitals and the sterilizing agents for the field water supplies.

The war has given a great impetus to the manufacture in this country of photographic developers, lenses, pharmaceuticals, synthetic perfumes, flavoring extracts, saccharin and numerous other products. Before the war, Germany and Austria supplied the world with the better grades of chemical apparatus and reagents. The United States bought many millions of dollars' worth annually of laboratory glassware. Since these importations automatically ceased we have been able to make our own glassware, which is now of a quality superior to that manufactured in Germany or Austria. We are also making an excellent quality of porcelain.

Before 1914 every pound of synthetic phenol came from Europe. Now a score or more plants are producing it in large quantities, chiefly for use in the manufacture of picric acid for war purposes. The September *Chemical Engineer* stated that the Edison works at Orange, N. J., is furnishing regularly 3,000,000 pounds of phenol per month.

At the beginning of the war, potash salts, for instance pearl ash, was selling at less than three cents a pound, and shortly after the price rose to $1.50 a pound, or more. Industrial establishments were obliged to use substitutes for all potash compounds or go out of business. Germany produced practically all of the potash at that time. To-day many methods are employed in this country to produce potash, some of which may well compete with the German products after the war.

Before the war, Germany made most of our colors used in textiles, leather, straw, feathers, paper, ink, pigments, varnishes, and for innumerable other products of our manufacture. At the present time we are ourselves manufacturing a quantity of color compounds equal to that used by us in normal times, and the number of colors produced is constantly increasing. Many concerns now manufacturing dyestuff intermediates have their own nitric acid, oleum, nitration, sulphonation, and acid-recovery plants.

With proper legislation we can manufacture on a competitive basis practically every chemical product which we now import. Cheap labor is not a factor of importance. The final selling price of the strictly chemical products imported into the United States annually before the war has been estimated by Gudeman (*Journal of Industrial and Engineering Chemistry*, February, 1915) at $250,000,000, of which not over four per cent represents labor value.

The tremendous advantage which Germany had at the beginning of the war has taken more than three years to counteract, and the result has been an awakening in other countries to the necessity of furthering the chemical and metallurgical industries in every possible way.

The Germans have for many years realized the grave necessity of furthering the work of the chemist and the chemical engineer for warfare, as well as for the necessities of industry in time of peace. They knew that by developing their enormous color establishments in peace times, they were producing factories which could be readily changed over to explosive works in time of war. They realized that the industries for the fixation of nitrogen used in fertilizers in time of peace could also be used for the production of enormous quantities of picric acid and trinitrotoluene in war time. They realized the necessity for acetone, synthetic phenol, industrial alcohol and all the numerous solvents and compounds used in peace as a still greater necessity for war.

The fact that strong corporations are entering the chemical manufacturing fields, indicates that capital

expects and feels a reasonable assurance that this country will properly further and sufficiently protect their interests after the war, in order that we may independently produce our own necessities and at the same time add new assets to the nation's wealth.

Precise Use of Figures

To the Editor of Metallurgical & Chemical Engineering

SIR:—I take the liberty of calling your attention to the extremely incorrect use of figures in the conversion table of Mr. Dwight Gerber in your issue of Jan. 15. In the example given, 5.5 lb. would be correctly expressed as 2490 g. But 5.5 lb. is different from 5.500 lb., for in the latter case the number of pounds is known to one-thousandth of a pound, while in the former case it is known only to the nearest tenth. This consideration shows the absurdity of converting 5.5 lb. to 2494.75835235 g. If 5.500000000000 lb. were converted to the number of grams given in the example there would be no criticism, but it is not very often that anything is weighed to this degree of accuracy.

Nickel-Chromium Wire

To the Editor of Metallurgical & Chemical Engineering

SIR:—The opinon seems to prevail to a certain extent, that the purchaser of an electric furnace employing nickel-chromium wire as its heating unit cannot secure a new unit with which to repair it when the wire burns out. We want to correct this erroneous impression.

It should be clearly understood that any concern or individual can buy units, in the form of coiled wire, having measured and definite resistance, with which to rewind any electric furnace built by a manufacturer licensed under the Marsh Patents. The user can purchase wire in this form and make the repairs himself.

These coiled units can be secured from the device manufacturer by giving him proper data, relative to the furnace to be repaired, such as Serial No., Type, Voltage, etc.

LICENSORS UNDER THE NICKEL-CHROMIUM RESISTANCE ELEMENTS PATENTS.

Laboratory Methods for Benzol-Recovery Plant Operation

To the Editor of Metallurgical & Chemical Engineering

SIR:—The following corrections and additions should be made to my article on the above subject published in your issues of Nov. 1, Nov. 15 and Dec. 1, 1917:

Method for the Determination of Light Oil in Gas.

Vol. 17, *No.* 9, *Nov.* 1, 1917, *pages* 550-551.

1. It is important that a complete blank test be run on the wash oil used. If the blank is high the oil should be thoroughly steamed out at a temperature of 160 deg. C. before using.

2. For passing gas through absorption apparatus, the rate of flow of the gas during the absorption should not exceed 2 cu. ft. per hour for benzolized gas, or 4 cu. ft. per hour for debenzolized gas.

3. In making steam distillation of oil from absorption apparatus, the temperatures given are in error. The oil should be heated until the temperature shows a temperature of 160 deg. C., and the temperature should be maintained between 150 deg. and 160 deg. C. throughout the steam distillation.

4. When testing unpurified water gas or other gas high in carbon dioxide, a tower of oxide and shavings is substituted for sodium hydroxide bottle in absorption apparatus (bottle No. 1, Fig. 1, p. 550).

The Analysis of Light Oil.

Vol. 17, *No.* 9, *Nov.* 1, 1917, *pp.* 551-555.

In Tables I and II, p. 553, under "Estimated by Method"—column headed "Benz. Lb." is in error and should read "Benz. C_6."

Method for the Boiling Point Tests of Benzols.

Vol. 17, *No.* 10, *Nov.* 15, 1917, *pages* 586-588.

The word internal was omitted in stating dimensions of diameter of vapor tube, so the third sentence in section headed "Flask" should read: "Half way up the side of the neck a vapor tube of not less than 5 mm. *internal* diameter," etc.

Sulphuric Acid Color Test for Benzol, Toluol, Solvent Naphtha, Etc.

Vol. 17, *No.* 11, *Dec.* 1, 1917, *page* 642.

The proportions of sulphuric acid and material to be tested are in error, and second sentence in second paragraph should read as follows:

"Sufficient concentrated (1.84 sp. gr.) sulphuric acid is put in to fill one-quarter of the bottle, and then twice as much of the material to be tested is added." The subsequent shaking and comparison are as stated.

Determination of Naphthalene in Oils.

Vol. 17, *No.* 11, *Dec.* 1, 1917, *pages* 646-647.

In making the determination of the free picric acid present, the quantity of benzol solution to be drawn from burette (page 647) is in error, and should be 1200

Causticizing Soda Liquors

To the Editor of Metallurgical & Chemical Engineering

SIR:—I am surprised to note the absence of comment on one or two slight mis-statements appearing in the article "Causticizing Soda Liquors" in your issue of November 15, 1917. The authors state that the Dorr devices were developed principally for use in the concentration of ore in which the carrying fluid has no value. They intimate that this is a detrimental feature in the use of the apparatus in the causticizing process. While it is true that the flotation process for ores has given the Dorr apparatus great prominence in the field of ore concentration, we must remember that the early development, and for many years the only development, of Dorr apparatus was in connection with the cyanide process in which the carrying fluid (gold-cyanide solution) is the valuable portion and the pulp is wasted. Here we have exactly the same condition as is found in causticizing plants. To those who have worked with filters and who have vainly attempted to produce "a small volume of weak wash liquor" it seems strange to find the filtration process so strongly advocated at the expense of a more simple and efficient procedure.

IVAN E. GOODNER.

Paradise, Calif.

Western Metallurgical Field

Selective Flotation at Eureka, Colo.

THE United States Smelting, Refining & Mining Company have purchased the Gold Prince property at Eureka, Colo., and since that time have conducted extensive experimentation on their complex sulphide ore, containing gold, silver, lead, zinc, copper and iron. Definite results have enabled their local manager, MR. M. H. KURYLA, to design and build a 500-ton unit of modern steel and concrete construction, illustrated in Fig. 1, and which will start operations in the spring.

The old Sunnyside mill was modeled along the conventional lines of using stamps for grinding, followed by amalgamating plates and a few tables to clean the overflow. The troublesome iron-zinc middling was later treated in Huff electrostatic machines. The difficulties that had been experienced in making a satisfactory separation between the zinc and the lead, demanded a search for a more efficient separation. This has been found in the selective lead flotation process now being tested in one of the old mills acquired with the property, and which has eliminated the necessity of the static treatment.

SUNNYSIDE 500-TON MILL

The ore will be crushed at the mine in two No. 6-K gyratory crushers, working in series; a 3-ft. x 10-ft. Sheridan shaking grizzly being used between the two crushers to sort out waste and to separate rock for tube mills. The crushed ore will be delivered to the new mill by a 16,000-ft. Trenton tramway, and weighed at the discharge terminal by a Merrick weightometer. There are three 1000-ton cylindrical steel storage bins from which ore is fed by pan conveyors to three 8-ft. x 6-ft. Marcy ball mills working in closed circuit with 6-ft. extra heavy Dorr classifiers. The Marcy discharge, approximately at 20-mesh, will be sampled by an automatic motor-driven sampler, which together with the other samplers in the mill will be actuated by a master clock. That ball mills are being installed in spite of the fact that 100 stamps were available from the Gold Prince purchase is significant of the outcome of the investigations concerning equipment to reduce the ore from 2^1_2 in. down to 20 mesh.

The fine grinding will be done in three 5-ft. x 14-ft. tube mills, using mine rock for pebbles, and one 5-ft. x 8-ft. ball mill. From present indications a considerable economy may be effected by using mine rock, which appears to be especially well suited for pebble grinding. The overflow of the tube mill classifiers will be amalgamated inasmuch as the tests indicate that quite a proportion of the free gold fails to float selectively with the lead. For the present stationary plates will be used.

The selective flotation of the galena, together with a majority of the gold, silver and copper, will be accomplished in one 6-cell, 18-in. minerals separation subaerated machine of the latest Australian bottom-drive type, and one standard 6-cell, 24-in. M. S. mechanical machine. The test-mill results indicate a very fair recovery of lead in the form of a concentrate assaying 65 per cent lead and 5 per cent zinc from a head containing 4 per cent lead.

The tails from the above lead machines will be floated in a 20-cell, 24-in. standard M. S. machine, in which a zinc concentrate will be produced assaying over 50 per cent zinc with less than 5 per cent lead.

Both concentrates will be passed over Wilfley tables, which will be mostly in the nature of pilots. A definite proportion of the final tail from the zinc machines will be passed over a Wilfley pilot table. To thicken the tailings two 40-ft. x 12-ft. Dorr tray thickeners will be used. The lead concentrate will be thickened in a 16-ft. x 8-ft. Dorr thickener and filtered in a 12-ft. x 3^1_2-ft. Portland filter. The zinc concentrate will be thickened in a 25-ft. x 8-ft. Dorr thickener, filtered in a 12-ft. x 9-ft. Portland filter and dried in an Argall dryer, the dryer being available from the old 100-stamp Gold Prince concentrator.

The mill is served by an outside incline track, while the more important floors will be served by electric platform elevators. The small amount of pulp elevating that will be required will be accomplished by means of air-lifts.

Technical Association of Pulp and Paper Industry Meets in New York

The third annual meeting of the Technical Association of the Pulp and Paper Industry was held at the Waldorf-Astoria in New York, Feb. 5 to Feb. 7. The banquet was held at the Hotel Astor on the evening of Feb. 6.

Tuesday afternoon was given over to a meeting of the executive committee and to conferences of chairmen of standing committees.

A general session was held Wednesday morning at which President Henry P. Carruth presided. At this session reports were made by the officers and standing committees, of which there are now fourteen covering all phases of the industry.

On Wednesday afternoon two separate symposia were

held, one on Acid Making and one on Engine Sizing.

At the symposium on acid making the milk of lime and tower system were thoroughly discussed. Mr. E. R. Barker, of Boston, Mass., one of the leading exponents of the milk and lime system, read an interesting paper on that system. Mr. G. D. Jenssen of the G. J. Jenssen Co., New York, presented the advantages of the tower system, chief of which he said was the lower temperature of operation and consequent higher absorption of SO_2. He said the heat of the milk of lime system was also especially objectionable in summer time. Mr. Clinton K. Textor of the Nekoosa-Edwards Paper Co., Port Edwards, Wis., read an interesting paper on some of the theoretical considerations involved. Others who discussed the subject were: P. A. Paulson, Kimberly-Clark Co., Neenah, Wis.; Martin L. Griffin, Oxford Paper Co., Rumford, Maine; H. R. Heuer, Wheat Paper Co., Petoskey, Mich.; S. E. Lunak, Interlake Pulp & Paper Co., Appleton, Wis., and H. F. Obermanns, Hammermill Paper Co., Erie, Pa. A more complete account of this session will be given in a later issue.

At the banquet on Wednesday evening, Judge Charles F. Moore acted as toastmaster, and speeches were made by Dr. Charles H. Herty, editor of the *Journal of Industrial and Engineering Chemistry*, and Arthur F. Sheldon, president of the Sheldon School of Business Science.

First Annual Meeting of Chemical Alliance, Inc.

The Chemical Alliance, Inc., was formally organized at its first annual meeting at the Hotel Biltmore, New York, on Wednesday, Feb. 6. About two hundred were present.

The meeting was opened at 10 a. m. by Horace Bowker, president of the old Chemical Alliance, which was a fertilizer committee exclusively, acting in an advisory capacity to the Government. Chairman Bowker reviewed the events leading up to the formation of the present alliance and the reasons for its inclusion of all chemical and allied industries. An account of this reorganization has been previously given in our columns. The Chemical Alliance, Inc., the present organization was formed on Dec. 4, as we have previously stated, to take over the work of the former Committee on Chemicals of the Council of National Defense. Chairman Bowker explained that the work is varied and complex, with respect to the different sections. The Acids Section has had to deal chiefly with problems of production for war purposes, as has also the Alkali Section. The Fertilizer Section, however, which is not directly engaged in producing war materials, has had to deal chiefly with internal problems in the industry, such as coal supply, etc. The organization as a whole is a group of allied industries to which the Government can go and get information on its problems. It has already helped the Government considerably and is ready to help now. When the war is over there will be just as pressing problems as there are at present.

Mr. Henry Howard, vice-president of the old Alliance, followed with a short speech, in which he said that the main problems were those of distribution, obtaining of raw materials and the furnishing of statistics to the Government.

Mr. Charles MacDowell, president of the Armour Fertilizer Works, and now acting in an advisory capacity to the War Industries Board, made a few remarks and urged the fullest co-operation between the Raw Materials and Statistical Divisions of the War Industries Board and the industries represented in the Chemical Alliance.

Chairman Bowker then said it was the controlling view of the present Board of Directors, elected at the organization meeting in December, that the Alliance should represent primarily producers, and no others at the present time. This is subject to modification by the directors at any time, as they have the authority, according to the constitution, to decide on the membership.

The secretary, J. Cameron Bradley, reported that 169 applications for membership had so far been approved. This number has now been greatly increased through further applications.

Mr. D. W. Jayne of the Barrett Co. offered a resolution that no action of the Board of Directors or of any committee shall be binding on individual members, without the consent of the members. The resolution was adopted.

The chairman said that the formation of a vegetable oil, fats and glycerine section was under consideration, as it had been requested by the War Industries Board.

After this preliminary general session the members were split up into their various sections for the election of section chairmen. The following were elected:

Acids Section—W. D. Huntington, vice-president of the Davison Chemical Co., Baltimore, Md.

By-products of Coal and Gas Section—D. W. Jayne, Barrett Co., New York.

Foreign Pyrites Section—A. D. Ledoux, New York.

Electrochemical Section—F. A. Lidbury, president of the Oldbury Chemical Co., Niagara Falls, N. Y.

Fertilizers Section—C. G. Wilson, Virginia-Carolina Chemical Co.

Miscellaneous Chemicals Section—A. D. Rosengarten, Powers-Weightman-Rosengarten Co., Philadelphia, Pa.

Alkali Section—J. D. Pennock, Semet-Solvay Co.

Domestic Pyrites and Sulphur Section—Charles MacDowell, president, Armour Fertilizer Works.

Dyestuffs Section—Election deferred as not enough members present.

The above selections were announced upon reconvening. Election of new officers of the Alliance then took place, which resulted in the election of the officers of the old Alliance, viz., Horace Bowker, president; Henry Howard, vice-president, and J. C. Bradley, secretary-treasurer. The meeting was then adjourned, but most of the Sections met at luncheon and made recommendations to their chairmen, the chairmen meeting at 3.30 p. m. in a general directors' meeting. (Section chairmen are members of the Board of Directors.) At this directors' meeting in the afternoon five directors at large were elected and matters of organization were taken up.

New York Sections of Chemical Societies to Meet

The New York Section of the American Electrochemical Society will hold a joint meeting at the Chemists' Club on Friday, March 1, with the New York Sections of the Society of Chemical Industry and American Chemical Society. An illustrated talk will be given on "A Chemist's View of the Native Industries of China," by H. K. Richardson.

Metallography of Aluminium

Preparation and Etching of Microsections

By ROBERT J. ANDERSON

RELATIVELY speaking, aluminium has been but little investigated in the metallographic aspect, at least not in any measure comparable with what has been done on iron and steel or copper and brass. It therefore appears safe to say that there exists no metallography of aluminium; references in the scientific literature are scattered and few. This condition appears to be very curious when the importance of the metal as a material of construction for engineering purposes is considered. There have been some comprehensive investigations of certain of the useful aluminium alloys[1] and of some not so useful, but as to the metal itself, i. e., commercial aluminium of say 99 and and over per cent Al, no thorough metallographic work has come to the attention of the writer. On the metal as such, the main work has been done by Brislee[2], while a late paper[3] promises information which should be valuable. Other miscellaneous and scattered data are available, but it appears that a metallography of aluminium is yet to be set forth.

Other than on the metallography of aluminium, there is still room for much work with this metal, as may be witnessed by the fact that one of its most important physical properties; viz., its density, required redetermination as late as 1911 (this work by Dr. Brislee). Knowledge as to the annealing of cold-rolled (partly amorphous) aluminium sheet is still rather vague, and accounts of tests in this regard would no doubt be appreciated.

On account of the large number of engineering uses to which aluminium is being put, it may be that the account in this article will be of interest. A technique for developing the internal structure of aluminium is not so easy as for iron or steel, brass or copper, which ordinarily engage the attention of the metallographic laboratory. Hence, special modifications of the usual metallographic methods must be employed if satisfactory results are to be secured. The present article describes methods for the satisfactory preparation and etching of aluminium microsections.

Pure aluminium when submitted for microscopic examination may be in the form of castings, cold-rolled or annealed sheets, slabs, bars, wires, shapes, etc.; in alloys, it may be in the same forms. As an alloying element, it may predominate or not; where it predominates, the methods hereinafter described for pure aluminium are in general satisfactory, but where it is subordinate to another metal, e. g., copper in copper-aluminium alloys (erroneously termed bronzes), methods and reagents for copper or copper-rich non-ferrous alloys are better suited. This article deals with the metallography of aluminium and its alloys where aluminium is the main constituent.

Preparation of Microsections.

The general plan of preparing a metallic microsection is about as follows: (1) selection and removal of a portion of convenient size; (2) grinding or filing a flat surface; (3) polishing that surface; and (4) development of the structure by etching. The ordinary methods of polishing steel microsections will not afford good results with aluminium. Aluminium being rather soft will flow under light pressure, and while a buffing or burnishing action will produce a high polish, which the metal readily takes, heavy pressure will cause blurring of the structure and even local surface hardening. This must of course be avoided.

If microsections from castings are to be examined, they are prepared by the ordinary methods, which are familiar to metallographers, but observing special precautions. When aluminium or its light alloys are polished on fine emery papers (French Hubert Nos. 0, 00, 000, 0000), the surface becomes very dark, in fact almost black; this darkening is ascribed to the emery particles working into the surface of the metal, and becoming embedded there.

A. G. C. Gwyer[4] has written as follows on the subject of polishing aluminium:

> The chief difficulty attendant upon the polishing of pure aluminium and its softer alloys is the trouble which is experienced with the retention in the polished surface of the metal of the emery from the finer grades of polishing papers, as it is practically impossible to remove it subsequently on the wet-polishing wheel. Professor Carpenter has obtained good results by the substitution of ordinary blotting-paper in the place of the final emery-paper, but the writer has never been able to achieve success with this method, and has, in fact, now abandoned dry polishing entirely. With the softest aluminium the writer has obtained excellent results following the procedure here given:
>
> (a) Fine file, kept thoroughly wet with paraffin oil.
>
> (b) No. 1 emery-paper, soaked in paraffin, on wooden board.
>
> (c) No. 2 emery-paper, soaked in paraffin, on wooden board.
>
> (d) Diamantine powder on cloth-covered polishing wheel, kept thoroughly moist with water and also maintaining the supply of polishing powder.
>
> (e) "Globe Metal Polish" on "selvyt" cloth, on polishing-board, rubbing lightly. It may be found on examination that there has been some appreciable surface flow, in which case it is necessary to revert to No. 2, or possibly even No. 1, emery-paper and repeat all the above operations. This does not, however, usually take very long to carry out, and only very light pressure with the hand is required. The final

FIG. 6—Sand-cast aluminium, microsection from gate; X 100 diameters

polish before etching for metallographic purposes should be effected with a little metal polish on the finger, rubbing very lightly.

This method, advocated by Gwyer, is very good as anyone who may try it will find. As to the use of blotting paper[5], the writer has never had any success with this material, and supports Gwyer in his abandonment of dry polishing. A method somewhat similar to that of Gwyer, but possibly more rapid, has been developed by the writer, and it has given satisfactory results. This is as follows: preliminary preparation may be carried out by leveling off the surface of a massive section with a plain fine file followed by dry coarse emery paper and then by No. 0 French Hubert. This should be followed by Nos. 00, 000, 0000 French Hubert in succession, but these papers are covered with a thin layer of paraffin. The paraffin film prevents the entrance of the fine emery particles into the metal, and gives a high mirror-like polish.

The finer emery papers are covered with paraffin by simply pouring melted paraffin on their surfaces, and removing the excess with a flat, warmed instrument such as a dull knife or a three cornered file. The fine emery papers may either be secured to wooden boards or fastened to revolving discs. After polishing on the finest grade of paraffin-covered emery paper, this is followed by polishing on a duck-covered board or disc with fine tripoli and water in order to remove the No. 0000 scratches. The tripoli causes darkening of the surface, but this quickly vanishes when the final polishing is done on fine broadcloth or old well-washed calico with a good non-alkaline metal polish.[6] This may be followed or not by further polishing with No. 3 levigated alumina, or the alumina may be substituted for the metal polish as desired. The above procedure has been found satisfactory, but no doubt various modifications could be employed which would serve as well or possibly better.

Aluminium, being soft, is worn away very rapidly, so that the pressure or rubbing should be light. What amount of pressure to use is of course incapable of definition, but a comparison of the practice employed and the results obtained will determine how hard to rub.

When thin aluminium sheets are to be examined, it is more difficult to obtain a good microsection than in the case of castings or thick slabs. The gages usually submitted for microscopy vary from No. 10 to 28, and in the case of gages from 18 to 28 the thinness of the metal makes preparation troublesome. Sections may be prepared by cutting a strip about 0.75 inch square, bending up the corners slightly so as to afford a means of holding the piece, and polishing in the usual manner. In the case of highly planished cold-rolled sheets, the metal is stiff and hard and also has, as such, a high polish, so that complete following out of the procedure outlined, from file to alumina, may not be necessary; here the coarser grinding may be omitted, and only the two finest grades of paraffin-covered emery paper, the tripoli, and metal polish used.

Microsections of dead-soft thin-gage sheets are difficult to prepare because the metal bends so easily under the lightest pressure; it is therefore almost impossible to retain a perfectly flat surface even if it is once obtained. Small wires can be held in small clamps made of electrician's fibre, as in the case of other metals and alloys. It may be said that aluminium and its light alloys can be rapidly polished by hand, and very good results obtained by that means.

Other methods have been described for polishing aluminium, and Brislee[7] mentions rouge for final polishing. Rouge has never been found satisfactory by the writer; it causes surface darkening, and is therefore not recommended. Polished surfaces vary with polishing powder employed, as is well known[8]; thus silver when polished with rouge is darker in appearance than when polished with white alumina, and the same thing is true in comparing aluminium microsections polished with these two powders. The theory of polishing powders while interesting cannot be discussed here, but the facts in the case are that alumina is more satisfactory than rouge for polishing aluminium.

Etching Aluminium Microsections.

Aluminium and aluminium-rich alloys have been etched by the use of sodium hydroxide, hydrochloric acid, and hydrofluoric acid. Sodium hydroxide has been stated to be satisfactory for developing the structure of alloys of aluminium with zinc, copper, and manganese, but this reagent usually leaves the surface of microsections covered with a black deposit. On rolled and drawn material, this deposit will have a banded appearance. This deposit, according to Rosenhain and Archbutt[9], is of a carbonaceous nature and can be removed readily by immersing the microsection in a weak solution of chromic acid, after etching in sodium hydroxide. This is illustrated in Figs. 1 and 2 after Rosenhain and Archbutt.[10] Fig. 1 is a photomicrograph of an alloy containing approximately 13 per cent Zn and 87 per cent Al, in the form of a 13/16-inch cold-drawn bar; the dark deposit has been completely retained. Fig. 2 is that of an alloy containing about 5 per cent Zn and 95 per cent Al, in the form of a 7/8-inch hot-rolled bar; the deposit has been partly removed.

Ordinarily, satisfactory results may be obtained by the use of both sodium hydroxide and potassium hydroxide, if the black deposit is removed by chromic acid.[11] Sodium hydroxide is used in various strengths from 5 to 20 per cent. Ten per cent cold aqueous NaOH has been employed by Carpenter and Edwards,[12] with an average etching period of from three to five minutes. After trying sodium hydroxide, potassium hydroxide, hydrochloric acid, and hydrofluoric acid for etching a wide variety of forms of pure aluminium and many of its alloys, the writer is of the opinion that hydrofluoric acid is the best reagent. Hydrofluoric acid introduced by Brislee[13]; his reagent was made up by adding one part of fuming hydrofluoric acid to eight of water. When an aluminium microsection is immersed in this reagent, there is a steady evolution of hydrogen, and as the etching proceeds the surface becomes dark-

[5] Mentioned also by Dr. Rosenhain as being used at the National Physical Laboratory, England; private communication August 24, 1917.

[6] After trying a large number of metal polishes on the market a polish called "Magic Metal Polish" was found to be very good; its composition is not known.

FIG. 20—Manganese-aluminium alloy; 1.65 per cent Mn, chill cast; X 100 diameters

ened, but this darkening is readily removed by an immersion for a few seconds in strong nitric acid.

If a 15 per cent aqueous solution of hydrofluoric acid is used as the etching reagent (made by diluting the ordinary laboratory reagent with water), an etching immersion of about one minute will develop the structure of cast aluminium. The progress of etching may be inspected microscopically or under a low-power lens, and if the structure is not sufficiently developed, the microsection may be etched for a longer period. The questions of strength of acid and period of etching are so very variable that no definite rules can be laid down, nor does there appear to be any necessity for such. Various strengths of hydrofluoric acid may be employed, and the etching period will vary with the strength of the acid. The stronger solutions work more rapidly, and this is a factor in routine work or where a large number of microsections are to be examined.

For containing the hydrofluoric acid, a stock solution may be kept in a paraffin bottle; and for etching, a small amount, say 30 cc., should be poured into a paraffin dish or into a paraffin-coated dish. After etching, the surface of the microsection may be washed in water and then dried in alcohol and ether in the usual way. When properly etched, aluminium is silvery-white in color, and the internal structure may be readily seen under the microscope.

Microscopic Structure of Aluminium.

Photomicrographs in Figs. 3 to 20 inclusive show various forms of aluminium and two alloys; the microsections from which the photographs were taken were prepared and etched by the methods described. Fig. 3 is a photomicrograph of cast-pig aluminium which was poured in a chill mold; freezing was rapid, and the usual allotriomorphic grains typical of pure metals in general are absent; what are present are dendrites, the arms of which are fairly well defined, and which approximate in appearance the frozen ammonium chloride of Rosenhain.[18] The branches or arms from the various crystallization centers are interlocked. Water frozen in street gutters and on sidewalks has at times a like appearance. Fig. 4 shows a photomicrograph of the same metal at the juncture of the dendrites and the allotriomorphic grains (these being common to the interior of the pig); the transition from one structure to the other is marked. Fig. 5 illustrates sand-cast aluminium of high purity; it consists essentially of allotriomorphic grains of aluminium with the impurities segregated to the boundaries; the same thing is shown in Fig. 6, but at twice the magnification. The large black patches are not identified; they may be occluded matter.

Chill-cast metal is illustrated in Figs. 7 and 8; the microsection was taken from a tensile-test bar which had been cast in an iron chill mold. The arms proceeding from various centers of crystallization are very marked, similar to Fig. 3 but quite different from Fig. 5. In Fig. 9, there is shown the appearance of cold-worked aluminium sheet (16-gage), rolled cold from a slab about 0.25-inch thick. No evidence of crystallinity is apparent, and the metal is evidently mostly amorphous; flow lines in the direction of work (from left to right) appear to be distinguishable. The results of annealing cold-worked aluminium are shown in Fig. 10, which is a photomicrograph of annealed 16-gage metal. The difference between Figs. 9 and 10 is plainly evident. Fig. 11 also shows the effects of annealing on cold-rolled aluminium sheet. The degree of cold work in the case of the sheet represented after annealing by Fig. 10 had been greater than in the case of Fig. 11 because of the larger grain size of the former; both samples had been annealed for 15 minutes at 540 deg. Cent. and allowed to cool with the furnace.

When aluminium is hot-rolled, its appearance will be not unlike that in Fig. 12; there is still evidence of crystallinity but the grains have been distorted due to the work. Possibly some self-annealing took place on the metal in question, as the rolling was finished hot—at about 300 deg. Cent. The evidence of partial crystallinity in this metal is better shown in Fig. 13, at a higher magnification. The effects of annealing on the

[18] See Fig. 20, Plate VI, Physical Metallurgy, 2nd ed., New York, 1917.

hot-rolled slab, shown in Figs. 12 and 13, is illustrated by Figs. 14 to 18 inclusive. Metal shown in Fig. 14 had been hot-rolled to a 0.25-inch slab and then annealed for 10 minutes at 485 deg. Cent.; recrystallization is partial but far from complete. Fig. 15 shows the results of annealing the same metal at 540 deg. Cent. for 10 minutes; recrystallization is plainly not complete, but has proceeded further than in Fig. 14. The effects of annealing at still higher temperatures are shown in Fig. 16, where the slab had been annealed at 595 deg. Cent. for 10 minutes, and in Fig. 17, where the slab had been annealed at 595 deg. Cent. for 60 minutes. Hot-rolled aluminium after annealing at 595 deg. Cent. for four hours is shown in Fig. 18, where recrystallization is complete and grain growth has proceeded.

A photomicrograph in Fig. 19 shows the appearance of sand-cast aluminium-copper alloy containing 4.90 per cent Cu, and chill-cast manganese-aluminium alloy containing 1.65 per cent Mn is illustrated by Fig. 20.

Cleveland, Ohio, January 11, 1918.

Fuel Oil Now Under License

A proclamation has been issued by President Wilson placing under license all manufacturers and distributors of fuel oil with sales of more than 100,000 barrels a year. The system went into effect Feb. 11. Fuel Administrator Garfield has compiled a list of activities which will have the preference in receiving supplies of fuel oil. The distribution will be under the direction of Mark L. Requa, head of the Oil Division of the Fuel Administration.

Gasoline and kerosene are not included under the term fuel oil and hence do not come under Government control at present.

The list of preferred activities follows:

1. Railroads and bunker fuel.
2. Export deliveries or shipments for the United States Army or Navy.
3. Export shipments for the navies and other war purposes of the Allies.
4. Hospitals where oil is now being used as fuel.
5. Public utilities and domestic consumers now using fuel oil (including gas oil).
6. Shipyards engaged in Government work.
7. Navy yards.
8. Arsenals.
9. Plants engaged in manufacture, production, and storage of food products.
10. Army and navy cantonments where oil is now used as fuel.
11. Industrial consumers engaged in the manufacture of munitions and other articles under Government orders.
12. All other classes.

The chief reason for the placing in effect of the licensing system is the lack of adequate transportation facilities due to railroad congestion and the use of many tank cars for other purposes. It is also necessary that railroads using fuel oil have a sufficient supply and army and navy requirements must be taken care of.

It is also pointed out that many ships which are normally used for transporting fuel oil have been diverted for other purposes and this helps to make the transportation problem more difficult.

Depolarization by Sulphur Dioxide

By M. de Kay Thompson and A. P. Sullivan

THE following is an extension of the work by M. de Kay Thompson and N. J. Thompson,[1] on the electrolytic oxidation of sulphurous acid. In the former investigation the current efficiencies of the oxidation of sulphurous acid were determined; in the following the object was to determine how much the voltage is lowered at the anode by the presence of sulphur dioxide. The object in using sulphur dioxide as a depolarizer would be primarily to save power, only incidentally to make sulphuric acid; consequently the question here taken up is of greater importance than that in the first paper.

The electrolytic cell used consisted of a porcelain vessel in which a porous cup was placed as a diaphragm. The cell was placed in a cooling vessel. The inside diameter of the cup was 3.8 cm., the height 12.7 cm., when a platinum anode was used. For the duriron anode[2] a larger cup was necessary, 5.6 by 15.4 cm. A copper cylinder surrounding the porous cup formed the cathode. Anodes of platinum and of duriron were used. The platinum anode measured 2.5 by 8 cm., giving a total area of 40 sq. cm.; the duriron 5 by 11 by 0.5 cm,, giving a total area of 123.5 sq. cm.

The top of the porous cup was closed by means of a rubber stopper, through which passed the anode, a glass tube for delivering the sulphur dioxide below the anode, a tube for the exit of the excess gas, and another tube for making connection with the standard electrode for measuring the potential of the anode. The standard electrode was mercury covered with mercurous sulphate in one-tenth normal sulphuric acid. This was connected in the usual way to the liquid of the anode portion by means of an intermediate vessel containing saturated potassium chloride, to eliminate the liquid potential. This electrode was measured against a hydrogen electrode with twice normal sulphuric acid. According to Ostwald Luther (3d Ed., p. 445), the cell

$$Hg\ |\ Hg_2SO_4\ |\ sat.KCl\ |\ 2nH_2SO_4\ |\ Pt + H_2$$

would have the electromotive force 0.692 volt. The value measured was 0.663 volt. Therefore the standard electrode used had the single potential —0.663 volt, referred to hydrogen as zero, the charge on the solution giving the sign. All single potentials are here given on this scale. The current and voltage were measured by Weston portable instruments. The voltage of the cell which consisted of the anode and standard electrode was measured by the Poggendorff method with a Lippmann electrometer. A Weston cadmium cell was used for calibrating the bridge.

The sulphur dioxide was made by dropping concentrated sulphuric acid from a dropping funnel onto sodium bisulphite covered with a little water, in a 500 cubic centimeter flask.

The first runs were made as follows: A constant current was passed through the cell and the potential of the anode measured against the standard electrode for a period of 20 to 30 minutes, without sulphur dioxide. This was done for the whole range of currents used. Then a similar series of runs was made with sulphur dioxide passing through the anode compartment. When this potential became constant it was as-

								Depolarization ceases	

sumed that the solution was saturated and that the maximum depolarization had been reached.

As the Tables I to IV show, runs were made with 10 per cent sulphuric acid and a smooth platinum anode, with current densities from 1.25 to 10 amp. per square decimeter. Above 10 amp. the dioxide did not depolarize the anode. With a 16.5 per cent solution of copper sulphate the platinum anode was not polarized at above 6.2 amp. per square decimeter.

These tables are summarized below:—

TABLE V—FINAL VALUES. SUMMARY
SMOOTH PLATINUM, 10 PER CENT SULPHURIC ACID

Current Density Amp. dm²		1 25	2 50	5 00	7 5	10
Potential of anode	Without SO_2	−1 180	−1 226	−1 325	−1 415	1 504
	With SO_2	+0 202	+0 111	−0 082	+0 017	−1 63
Depolarization		1 38	1 34	1 41	1 43	None

SMOOTH PLATINUM, 16.5 PER CENT COPPER SULPHATE

Current Density, Amp. dm²		1 25	2 50	5 00
Potential of anode	Without SO_2	−1 308	−1 446	−1 612
	With SO_2	+0 193	+0 099	−0 042
Depolarization		1 50	1 55	1 65

With smooth platinum there is therefore a reduction in the voltage of the anode of about 1.5 volts for both sulphuric acid solutions and for copper sulphate solutions, if a certain current density is not exceeded. This current density is between 7.5 and 10 amp. per square decimeter for sulphuric acid and is less than 7.5 amp. for copper sulphate.

This is not in agreement with the observations of Mr. M. R. Thompson,[3] who found sulphur dioxide ceased to depolarize at a current density of 3.23 amp. per square decimeter (30 amp. per sq. ft.), using a platinum-black anode in a solution of copper sulphate, sulphuric and sulphurous acid. When the dioxide ceased to depolarize the voltage increased by 1.5 volts, which agrees with our results, except in our experiments this did not take place at such a low current density. Also Mr. Thompson's single potentials are both several tenths of a volt more positive than ours; the differences between are not affected by this. It is possible the platinum-black electrode used by Mr. Thompson is the cause of the difference, though platinum-black would be expected to depolarize better than smooth platinum.

That the metal of the electrode does determine the current density at which depolarization ceases to take place is shown by the results with duriron, which are given in table VI.

In this table the results were obtained by a different method of measurement. The current given in the first column was applied for one-half minute, and the anode potential then read. The next current applied for the same time, and so on. A similar series was then made with sulphur dioxide.

TABLE VI—POTENTIAL OF A DURIRON ANODE, REFERRED TO HYDROGEN AS ZERO, IN A SOLUTION CONTAINING 10 PER CENT SULPHURIC ACID AND 16.5 PER CENT COPPER SULPHATE $CuSO_4$. TEMPERATURE, 12° TO 13°C.

	Without SO_2	With SO_2, Volts	Depolarization
Amp. dm²	Volts		
0 405	−1 46	−0 264	1 14
0 810	−1 510	0 359	1 15
1 22	−1 581	0 416	1 16
1 62	−1 62	0 471	1 15
2 43	−1 667	0 565	1 09
3 25	−1 707	2 073	None
4 05	−1 721		

If results could be obtained in practice as favorable as in these small scale experiments, it is evident that considerable saving would result from the use of sulphur dioxide as a depolarizer.

The Need for Organization in New Chemical Companies*

By FRANK HEMINGWAY

A MATTER that has been uppermost in my thoughts for the past year or so is the lack of organization in many of the new large chemical companies and the necessity of bringing order out of chaos before going much further with the present attempts to bring about nation-wide co-operative effort.

Nearly all of you here to-night are engaged in established and already highly organized industries, and would be apt to class as fairy tales a simple and unexaggerated statement of just a few of the things that have happened in the last three years and are happening to-day, particularly in an industry with which I have been in close touch for some time past, namely, that of the manufacture of coal-tar intermediates and dyestuffs.

Our visit yesterday to the wonderful plant of the Laclede Gas Light Company encourages us to believe that the manufacturers of coal-tar derivatives in this country have little or nothing to fear to-day, or after the war, in the face of world competition. But when we get to the next link in the chain—that is, eliminating the uses of the coke, the town gas and the sulphate of ammonia, and consider what is done with those products described as coal-tar derivatives—we must acknowledge, if we are to be honest with ourselves, that as regards the next two steps, first, the production of intermediates, and second, the manufacture of finished dyes, we are a long way from home.

We may look with just pride on the wonderful progress that has already been made, but to employ a business term, the real progress is decidedly "spotty."

Nothing in the development of an industry of national importance is such a handicap as wrong-minded public action, based on ill-informed public opinion, and I fear that the public generally, and indeed many members of the chemical profession itself, have based their opinion of recent developments on what they have read or heard of the successes made by those old established companies which have made a success and of one or two of the newer organizations which have succeeded.

They have not had presented to them the long list of failures, nor have they any idea of how close to the wind many of the newer chemical industries are sailing to-day, despite the price advantages they enjoy. It is interesting and extraordinarily instructive at this time to read carefully the history of the failure of the British dyestuff industry within a decade or so of the time of Perkin's discovery of mauve in 1856. The financiers and business men in those days blamed the chemist as being an impractical man, and claimed that what little success had been made was due to their own efforts as business men and to the work done by their engineers. The chemists blamed the financiers and the business men, and indeed everybody but themselves, and they all joined in one general condemnation of their government. But one fact stands out, namely: that the most important factor of all was, as I have already expressed it, wrong-minded public action based on ill-informed public opinion.

However, we may claim to an extent that through the work of some of the members of this Institute, and particularly of men like Dr. Charles Herty, the American public is much better informed today than was the British public in the sixties and seventies.

I shall not touch at any length upon that subject which is uppermost in the minds of the members of this Institute, namely, the ethics of the profession, beyond venturing to say, at the risk of making myself very unpopular, that a great deal has been done in the last three years without consideration to professional ethics and business honor. Capital has sunk many millions in enterprises on the advice of professional men who had nothing more than a book knowledge of the particular industry; and, as a consequence, capital today is not so entirely happy about the future of our great chemical industries as it would have been if all their advisers had governed their action by the code of ethics which this Institute has adopted; and although we have not caused these troubles, it seems to me that for the country's good we should do all in our power to correct them wherever possible.

Most of us have heard and used the expressions, "co-operation," teamwork," and so on, until we are heartily sick of them. It has been my experience that business associations are formed with great enthusiasm; the heads of the important companies are all present at the first meeting; the officers are elected; committees are formed; days are spent over the by-laws; much is said about co-operation, and then the big men hand the thing over to their juniors, and little further progress is made. We hear the same old platitudes and vintage bromides, and we know perfectly well that the same old competitive antagonism continues to a large extent.

Surely, the head of the biggest corporation in the world, Judge Gary of the United States Steel Corporation, realized this when he instituted the Gary dinner. There is nothing illegal or in violation of the Sherman Act about men becoming first acquaintances and then friends. What happens when competitors become friends? Not necessarily an illegal price agreement, but a full, frank, honest and open discussion of their common problems.

In the first year of the war such a coming together would have been impossible. Had it been possible there is no question that the aniline oil fiasco would have been avoided. Within an interval of a few months aniline oil dropped from exorbitant prices to less than cost.

I ask you, would men who through their friendships had gained some knowledge in advance of what was likely to happen, have deliberately entered the aniline oil business in those early days? Precisely the same thing happened in phenol.

*An address delivered at the St. Louis meeting of the American Institute of Chemical Engineers, December, 1917.

This kind of competition is the greatest of all business disasters. It results in the closing of plants, the freezing out of the small men, the profitable continuation of the operation of the concern that is financially very strong, and nine times out of ten, as a result of such a business upheaval, with its attendant casualty list, no true technical progress is made.

Our German friends met their problem in a very different way. If a German manufacturer found himself undersold, he concluded that in all likelihood one of two things had happened, either that his competitor had a better and more economical method, or was obtaining his raw material cheaper, and it seems to me that most of them never paused in their efforts to simplify, improve and cheapen their processes.

Now, as I said in the beginning, all this may sound elementary, even rudimentary, to those of you engaged in fully established and highly organized industries, but I want you to realize that tens of millions of dollars are invested in chemical industries in this country under conditions that amount to chaos, and I ask you is it right for us to view calmly the sacrifice of so much capital, so much plant, and so much human effort, even though it may have been ill-directed at the start?

Many of you may think I am drawing the long bow when I make the unqualified statement that I know of many companies of large size whose boards of directors are composed wholly of financiers and business men possessing no chemical knowledge whatsoever, and in which there is no co-ordination between the directing head, the chemists and engineers, or chemical engineers, the sales department and the purchasing department. Companies hear that there is a good and profitable market for a certain product, and after full discussion with their head chemist—who, of course, should be able to produce any chemical product whatsoever; indeed that is what he is paid for—decide to start the manufacture.

There are innumerable instances of large companies that in good faith have entered into contracts for the sale of products which their chemist told them they could produce, only to make cash settlements after months have passed, and the realization was forced upon them that they were unable to produce the goods with the technical knowledge at their disposal.

Yet such concerns blunder along from one mistake to another without taking the simple and obvious step of bringing about co-operation among their own departments and placing on their board the best and most highly trained technical men that they can find.

Surely a scrutiny of the directorate of the leading and successful German chemical companies would at least indicate to these gentlemen that the success of the German industries had to a large extent been brought about by the prominence given in the management of their affairs to men of scientific attainments. It is hard to believe that with such conditions of complete lack of co-ordination or effort under their very noses, in their own establishments, these very gentlemen will give time and thought to such matters as governmental action. It looks like getting the cart before the horse.

About two weeks ago I had the pleasure of entertaining Dr. M. O. Forster, technical director of British Dyes, Limited, and of bringing him together in a social and informal way with the heads of several of the important companies manufacturing intermediates and dyestuffs. Dr. Forster spent a month in this country studying the development of the industry here, and, as I understood him, with one thought in mind, namely, the future of the industry in America, in France and in England, and what was likely to happen after the war. He felt that in the fact that the countries of the Allies could not possibly produce a full line of dyes before the end of the war lay the great danger, for the Germans would sell their small tonnage specialties to American buyers only when the buyers purchased the full line. This condition is described in business as "full line forcing." There is a provision against this in the Clayton Act, and it seems that the crux of the whole matter will be in the enforcing of that provision.

It is evident, however, that some of the larger companies in this country are practising in their domestic trade the very evil against which they seek to protect themselves by legislation. We know of smaller concerns that are producing specialties that are of a better quality than the same product manufactured by the larger companies making a fuller line, but are unable to place them under contract because the buyers fear to split their business lest the larger companies keep from them their full line.

This in itself is a delicate situation, which I maintain would be avoided with advantage to all had all the manufacturers come in personal contact and acquaintance ripened into friendship and led to free discussion.

I fear I have wandered from my subject, which has to do simply with the lack of organization in some of the newer industries, but I could not resist the temptation of touching on these other matters.

To summarize the conclusions I have drawn from my observations in the last three years, I might say first that the members of such an influential body as the American Institute of Chemical Engineers should individually do all in their power to hold the confidence of the public, the business men and the financiers in the development of the newer chemical industries, and to offset as far as possible the damage that has been done by the action of professional men not qualified to advise on particular industries, but who nevertheless have not hesitated to involve large sums of money in development. Second, that for the nation's good the individual members of this Institute should do all in their power, and without regard to their own pecuniary advantages, to educate public opinion, the business men, and the financiers, to a correct understanding of the problems they face, with a view to bringing true scientific and technical order out of the chaos which exists in so many cases, and to make clear in fact to some of the more complex organizations that although the solution of one technical problem is important, it is more important to first perfect the co-ordination of all departments so that finances, business policy, scientific control, utilization of waste products, sales and purchases, work together as a solid unit to grapple and solve all problems presented.

115 Broadway, New York.

The Nichols Medal for 1917 has been awarded to Dr. Treat B. Johnson of the Sheffield Scientific School of Yale University. The presentation will be made on March 8, 1918, in Rumford Hall, Chemists' Club.

Efficiency in Industrial Research

By Charles W. Hill

THE establishment of many new industrial research laboratories in this country during the past two years, especially by concerns not directly connected with war products, will be noted with satisfaction by technical men. However, it is to be regretted that many of the older laboratories are not operating on a high plane of efficiency and that many of the newer ones have been started as experiments without due consideration of the experiences of the older organizations. The time appears to be ripe for a discussion of the various factors which influence the efficiency of industrial research, and for crystallizing the experiences of those who have been engaged in such work for some time, so that new laboratories may avoid the errors of the old and that the efficiency of others may be increased.

The following may be mentioned as among the more important factors: the relation of the laboratory to the general organization, the attitude and policy of the management, the selection of laboratory director, the selection of research men, problems and methods of work, and details of laboratory management.

Relation to the General Organization

The efficiency of a laboratory seems to be influenced in no small degree by its position in the general plan of organization of the company. The arrangement which is almost certain to give the best results constitutes the laboratory as a separate department occupying the same relative position in the organization as that of the production or sales departments, with the laboratory director responsible to the general manager. As a rule, the interposition of officials between the general manager and the director tends to lower the laboratory efficiency, although there appear to be exceptional cases where such an arrangement may not seem feasible.

A somewhat common and invariably a serious mistake is that of placing the laboratory under some branch or department of the concern. Frequently it is placed under the factory or production management. The idea back of such an arrangement is the fact that many if not all of the problems relate to the factory in some way or other. Experience shows that this is the very reason why the laboratory should not be under the factory management. It should be absolutely free from influence of a compulsory nature from any source, be it factory, sales or purchasing departments. Its success is attendant on the full co-operation with all branches of the organization; and this is best obtained when it is subject to none of them.

The attention of the writer was called to a large laboratory which is under the factory management, a large part of its time being devoted to rendering aid to a weak factory organization. Although the process is one of many years' standing, continuous help is required of the laboratory to maintain production, without the laboratory being allowed to make the changes necessary to place production on a firm basis. At the same time, each laboratory man is cautioned against breathing a word about actual factory conditions to anyone outside the factory management. If this laboratory were independent of the factory, it could soon bring about the desired changes in factory affairs. The benefits thus to be derived by the company as a whole, by the factory and by the laboratory, are obvious. The position of this laboratory in the general organization prevents it from doing good where it is most needed.

Attitude and Policies of the Management

The attitude and policies of the management regarding the laboratory are naturally of the utmost importance. Some managements expect a laboratory to be an immediate source of profit to the company. They sometimes expect wonderful and profitable results within a very short time and with a relatively small expenditure. As a rule, this can not be. It would be a sad commentary on the factory and technical men who have been in the business many years if a research laboratory could uncover startling discoveries regarding an old process in a short period of investigation. If money-making discoveries are possible with a small expenditure of time and money, every research man in the country would be experimenting on his own account in his cellar or attic if he could not afford a better place. Barring virgin fields, industrial research does not, as a rule, bring immediate results commensurate with the cost. It is therefore necessary for ultimate success that the general management foster research generously and wait a reasonable time for returns. One may possibly secure some profitable returns within two or three years after a well equipped laboratory is in full swing. Industrial research resembles mining. One must clear away the site, get down to the ore and get the machinery running before our mine will pay a dividend. The pay-dirt is seldom on the surface.

A niggardly policy in the matter of securing apparatus for efficient work and of paying salaries necessary to engage and retain men of quality results in inefficiency and unsatisfactory returns. This does not mean that one should go to the other extreme of unlimited expenditure and no accounting of progress to the general management. Any fair-minded director stands ready at any time to take the responsibility for his methods and expenditures, provided he is given authority over them; but he cannot successfully direct research if he is required to fight for each piece of apparatus or every increase in salary for his men.

A rather generous policy regarding the men in the laboratory is usually productive of the best results. This applies to such matters as working conditions, of hours, vacations and clean, healthful laboratories and offices, the publication of papers not of secret value, financial assistance to men attending meetings, etc.

The Selection of Director

The selection of a director is a vital matter in the establishment of a laboratory, and it is one in which a company can easily make a mistake. A common error is to transfer a chemist or engineer from routine or factory work into research work as a director. Another mistake is the selection of a man who has made a reputation in individual research but who has not had experience in working with or directing the work of others.

The personality of a director is of importance sec-

ond only to proper training and research experience. A director should be a good judge of men and able to manage as well as to inspire them. He should be a leader rather than a driver. Furthermore, he should be a man who is inclined to be independent and not in the least fearful for his own position. This enables him to present the requirements of the laboratory to the management and if necessary put up a good fight to carry through those matters which he knows are important. Being certain of his own standing, he can allow credit to fall on the men under him, taking his own credit for the harmony and general efficiency of the laboratory as a whole. Since his men look to him for advancement, he must be able to judge the merits of the individual and his work and not be influenced by "taffy" or design.

Selection of Research Men

As a general proposition, it is cheaper and more satisfactory to engage experienced research men than to train novices. A successful organization consists of experienced research men in charge of the various divisions of the laboratory with younger and less experienced men as their assistants.

The personality of the research man is of great importance. Men should be chosen carefully, and all should be on a kind of probation basis, especially with reference to their attitude and their ability to fit into the organization. Men who do not mix well with the others, who start dissension, who "blow" or "bluff" or who are confirmed "knockers" should not be retained on the staff. Good laboratory spirit and teamwork is of inestimable value and unfortunately is not always found in industrial laboratories.

In engaging new men, it is better to pay them the salary they ask if it is not unreasonable and to impress them with the necessity of demonstrating their self-appraised worth than force them to accept a lower salary than they feel they deserve. When true merit is involved, the greater returns due to proper spirit of the worker and his aim to make good will more than balance the difference in salary.

Problems and Methods of Work

The nature of the problems to be investigated by a particular laboratory will naturally depend on the extent of fundamental information in possession of the company regarding its process and products. Usually a new laboratory finds many problems of a practical nature awaiting solution. Factory problems as a rule give the laboratory a higher percentage of positive results than do other classes of problems, and hence they afford greater opportunity for returning a good profit to the company for the minimum of effort. However, it is a serious mistake to limit a laboratory to such problems. A certain proportion of men should be engaged with problems of a fundamental nature which carry the investigator into new fields. Such work is the most probable source of new processes or products which can be protected by patents and which protect the company against future competition in its field. Where necessary for the complete understanding of a practical problem, it is profitable to carry a certain amount of theoretical experimentation. There are those who argue for a complete separation of the two kinds of problems, even going so far as to maintain entirely separate laboratories. This would seem to the writer to be a rather arbitrary division and usually not to be advised. It is often highly desirable for the man on a practical problem to conduct theoretical experiments for some time, and it is often as desirable, if not necessary, for the experimenter on so-called pure research to follow the practical applications of his discoveries. It is difficult to see any reason for the attempted division. A well organized research laboratory has its analytical division which can be made large enough to handle the necessary control work for the factory, and there is a distinct advantage in having the control laboratory free from the factory.

There is no good reason for the objection of some investigators to so-called practical problems other than the fact that they frequently lead to results which cannot be published on account of their commercial value. There is, however, a serious objection to the manner in which some managements desire such problems to be handled. Regardless of the nature of the problem, scientific methods of research should be applied with smallest practical amount of the cut-and-try variety of research. Here is the place where officials have been known to interfere with the laboratory to the detriment of research and with loss to the company. It is an interesting although unpleasant fact that some managers, who would unhesitatingly swallow whatever medicine a physician prescribes, will attempt to prescribe methods of research to technical men of far greater comparative training and experience than possessed by the physician. Regardless of the nature of the problem, suitable equipment should be provided and proper methods of research should be followed.

Processes developed in the laboratory should be expanded to a semi-factory basis before final adoption in the factory. When they are finally placed on a factory scale they should be operated for a time by the laboratory before the regular production department takes charge. A division of responsibility or the introduction of research problems into the factory in this connection is likely to cause trouble.

Details of Laboratory Management

Cost Accounting

In all laboratory work fairly accurate records should be kept of the cost of time and materials. This enables the management to control the amount expended on any problem, and at the same time gives the laboratory credit for time spent on factory troubles and consultations which would otherwise be charged to research. There are three common methods of laboratory accounting. According to the budget system, the management appropriates a sum of money to cover all research expenses for a given period and makes the director responsible for the distribution of the total appropriation among the various problems. Frequently a separate appropriation is made for apparatus. The appropriation system is the budget system applied to individual problems, each problem being granted a sum of money and being assigned a time limit. When either the time or the money has been used, a further appropriation is required before the work progresses. According to the third system, accurate accounts are kept of the cost of each of the more important lines, and the monthly expenses of the laboratory are distributed among the various accounts. The manage-

ment may then urge expansion on some problems or the curtailment. The particular method of financing the laboratory does not seem to have any great effect on its efficiency, as long as the proper apparatus is supplied as needed, and as long as some accounting system is used.

OUTLINING OF WORK

Regardless of the experience of the individual worker, it is always advisable to have his work outlined in advance. This is not only better for him, but it affords a reliable record for patents in the case inventions arise from the work. Two systems commonly used are the Conference System and the Proposal System.

In the former, the subject of a research is discussed in a regular weekly or monthly conference among men from the laboratory, factory and patent department; stenographic notes being taken of the discussion. Results are presented by the research man and further work is planned by the conference. There are several objections to the system, of which may be mentioned the loss of time through arguments and futile discussions, the difficulty of directing discussion and of reaching a clear-cut decision, the loss of time in consideration of hastily made suggestions, and the feeling among many research men that the system removes personality from their work. Even the best conducted conference system is likely to follow the research more than direct it. This system alone does not appear to be as satisfactory as the combination of it with the proposal system.

According to the latter plan, a proposal for research is made by the research man and approved by the director. This consists of an outline showing the object of the proposed work, a reference to the previous work leading up to it, a statement of the principle or theory involved, an outline of the variables to be studied together with tests and methods. This outline may be made after conference with the director and others interested in the problem. When the proposed work is completed the results are summarized and further proposals made. Conferences are held when the research man is in need of suggestions as to methods of attack or of information from certain departments. Suitable arrangements are usually made for handling small problems and rush jobs without a proposal; but if such work involves much time or expense it should be outlined. An experienced investigator usually outlines his work and so does not object to submitting his outline for record. Some inexperienced research workers have been known to object to the proposal system and have urged that they be allowed to proceed without direction. This would obviously be dangerous for them as well as for the laboratory.

REPORTS

Reports should be carefully and completely written, and as their volume increases, abstracts and cross references should be made. The amount of useful data which can be buried for years, duplicated or misapplied because of faulty reports is often as surprising as it is disheartening. The cost of properly recording a piece of research so that it will be of value in future years is usually an insignificant part of the total cost.

Industrial research eventually pays and pays liberally if properly executed. It not only assists in raising the quality of a product and in lowering the cost, but it is the source of new products, new applications of old products, and of improvements and inventions which safeguard the future of an industry. It benefits the sales department by furnishing technical information and it inspires in the sales force a confidence in the leadership of their firm. It is a necessity in a modern business of magnitude, and has proved its worth even under unfavorable conditions. Its greatest possibilities are attained only under the proper conditions of management and surroundings, some of which have been outlined in the above discussion.

Pittsburgh, Pa.

Explosives and Ingredients Requiring Licenses

The Bureau of Mines has issued a list of articles requiring licenses under the Act of Congress prohibiting the manufacture, distribution, storage, use and possession in time of war of explosives and ingredients thereof. The list follows:

Explosives

Ammonium nitrate.
Blasting powder.
Caps:—Blasting, detonating, percussion—all classes.
Detonating fuse, or cordeau detonant.
Detonators.
Dynamites.
Electric blasting caps and electric detonators.
Fireworks and flash-light powders.
Fulminates.
Fuse of all varieties.
Gun cotton.
Gun powder and gun powder mixtures (except small arm or shot gun cartridges).
Nitro cellulose and nitro glucose.
Nitro glycerine (except in official U. S. Pharmacopoeia solution, or in form of pills, or granules containing not more than 1/50 grain each).
Nitro-glycol, -mannite, -starch, and -sugar.
Permissible explosives.
Ammonium picrate.
Picrates.
Picric acid.
Smokeless powder (except small arms and shot gun cartridges).
Trinitrotoluol.
Trinitrocresol.
Trinitronapthaline.
Tetranitroaniline.
Tetranitromethylaniline.

Ingredients

(List approved Jan. 5, 1918)

The purchase, possession, sale or use of anyone of the ingredients herewith listed below in amounts of *one ounce or over* requires a Federal Explosive License.

Bichromates:—Ammonium, potassium, sodium.
Chlorates:—Barium, potassium, sodium, strontium.
Chromates:—Ammonium, barium, calcium, chrome green, chrome yellow, lead, potassium, sodium.
Nitrates:—Ammonium, barium, copper, ferric, lead, magnesium, nickel, potassium, silver, strontium.
Nitric acid:—Aqua fortis, fuming, nitric acids of all grades and strengths, mixed acids.
Perchlorates:—Perchloric acid, potassium.
Perborates:—Magnesium, sodium, zinc.
Permanganates:—Calcium, potassium, sodium.
Peroxides:—Barium, calcium, magnesium, oxon (cubes and cartridges), sodium, strontium, zinc.
Phosphorous.

Licenses may be obtained from local federal licensing agents. Application must be made in person by duly authorized officers of companies. The licensing agent for New York is J. R. Healy, Municipal Bldg., and for Brooklyn, John F. Dixon, 365 Jay Street, Brooklyn.

The Third Annual Lyons Fair will be held March 1 to 15, 1918, at Lyons, France. The first two were held in 1916 and 1917 and were very successful. No American companies participated in 1916, but in 1917 thirty-three concerns were represented. This year a much larger representation is expected. Mr. George B. Van Cleve, 1790 Broadway, New York, is chairman of the American Committee.

Grain-Size Measurements

By Zay Jeffries

MANY grain-size determinations by the method described by the writer, A. H. Kline, and E. B. Zimmer* have led to certain refinements in manipulation. Of the several methods tried, the following is recommended as the most satisfactory:

A circle 79.8 mm. diameter is drawn on the rough side of a ground-glass screen, the center of the circle being near the center of the rectangular section of the screen. This ground glass is mounted in a frame which fits a metallographic camera, the smooth side of the glass being on the outside. When the image of the specimen for grain-size determination is focused on the screen the circle will be plainly visible and its circumference should be well within the image.

When the image is properly focused the grains intersected by the circumference of the circle are checked and counted. Since the check marks must be made on the smooth side of the glass, a soft red pencil such as is used in laboratories for marking beakers and flasks will be found satisfactory. The marks used to indicate the boundary grains are usually short, straight lines intersecting the circumference of the circle and perpendicular to it. The completely included grains are next checked and counted, after which the red marks are erased from the glass with a dry cloth. The specimen can then be moved and other measurements made as desired. The idea of putting the rough side of the ground glass with the circle drawn on it to the inside of the camera was suggested by W. T. Burgoon.

In the early experiments the equivalent number of whole grains within the circle was obtained by adding 0.6 of the boundary grains to the completely included grains. The factor 0.6 was used as the result of about 200 determinations which showed an average factor of 0.58. The accuracy of the work involved did not justify the use of a factor of two figures, so 0.6 was chosen in place of 0.5.

I am pleased to state that further careful measurements show that the factor 0.5 is actually more nearly correct than 0.6. The factor 0.5 is more convenient to use, since the boundary grains (usually less than 50) can be divided by 2 instead of multiplied by 0.6. It is true that either factor gives results somewhat more accurate than a specimen can be sampled and in some cases more accurate than the grains can be distinguished, but we now have experimental justification for using the more simple factor.

*Trans. A. I. M. E., Vol. LIV, pp. 594-607. The author's method is recommended by the American Society for Testing Materials, *Proceedings*, Vol. XVII, 1917, Part I, Tentative Standards.—Editor.

TABLE I

Magnification Used = m	Diameter of Circle in Millimeters	Multiplier to Obtain Grains per Square Millimeter = f
Full size	79.8	0.0002
10	79.8	0.02
25	79.8	0.125
50	79.8	0.5
100	79.8	2.0
150	79.8	4.5
200	79.8	8.0
250	79.8	12.5
300	79.8	18.0
500	79.8	50.0
750	79.8	112.5
1000	79.8	200.0
1500	79.8	450.0
2000	79.8	800.0

The use of the factor 0.5 in place of 0.6 does not in any way affect the use of the table of multipliers from which to obtain the number of grains per square millimeter at any given magnification. If the equivalent number of whole grains within the circle measured at a certain magnification be multiplied by the number in the third column of Table I opposite the magnification used, the product will be the number of grains per square millimeter.

A circle 79.8 mm. diameter has an area of 5000 sq. mm. If it is desired to use a rectangle in place of a circle for the determination, convenient sizes will be found in Table II.

TABLE II

Convenient Sizes of Rectangles for Grain-Size Determination

70.7 x 70.7 millimeters	55 x 91 millimeters
65 x 77 millimeters	50 x 100 millimeters
60 x 83.3 millimeters	

Since each of these rectangles has an area of about 5000 sq. mm., the multipliers given in Table I can be used for any of the rectangles in Table II, or any other rectangle having an area of 5000 sq. mm. To make a grain-size determination, with a rectangular in place of a circular area, the grains intersected by the periphery of the rectangle should be counted, one-half the number added to the completely included grains and the result will be the number of equivalent whole grains within the rectangle. If the determination is made at one of the magnifications given in Table I, the number of grains per square millimeter can be obtained by multiplying the equivalent number of whole grains within the area by the multiplier (f) opposite the magnification used. The rectangle could be used on a ground glass as described above for the circle or it could be used on a micrograph.

Brass metallographists do not use the magnifications given in Table I, so a separate table would be necessary for their purposes. Also, some metallographists prefer to refer to the grain size in terms of the diameter of the average grain in millimeters or the area of the average grain in μ^2. The following simple formulas will be found helpful in these cases.

w = boundary grains.
z = completely included grains.
x = equivalent number of whole grains in 5000 sq. mm. (circle 79.8 mm. diameter or rectangle having area of 5000 sq. mm.).
m = magnification used.
f = multiplier to obtain grains per square millimeter
n = number of grains per square millimeter.
d = diameter of average grain in millimeters.
a = area of average grain in μ^2.

$$x = \frac{1}{2} w + z$$

$$f = \frac{m^2}{5000}$$

$$n = fx$$

$$d = \frac{1}{\sqrt{n}}$$

$$a = \frac{1{,}000{,}000}{n}$$

Some General Aspects of Evaporation and Drying*—II

By Hugh K. Moore

(*Concluded from page* 133)

Phenomena in an Evaporator Tube

THERE is a limit also to the amount of evaporation which can be done in a tube in comparison to the volume of liquor circulating through the tube. Generally speaking, the economical operation of such evaporation is limited to that point where incrustation on the tubes due to evaporation commences. It may be asked why this point should arise, or why an evaporator should be run in such a way as to approach this limit, when we know that as we approach it we add operating and mechanical difficulties to those which we already have in sufficient abundance. The answer is that unfortunately some liquors have such foaming tendencies that no way has yet been discovered to evaporate them without conducting the operation in such a manner as to make this point of vital importance. As an illustration it might be said that the writer had designed, built, and operated evaporators with tubes 2 in. in diameter and 7 ft. in height, and in which the liquor inside the tube rises only 3 in. above the bottom tube sheet. These levels, of course, were measured before steam was turned on and ebullition commenced. Foam, in the sense as used in evaporation, may be considered as a globule of vapor surrounded by a film of liquor. By keeping the level of the liquor low in the tubes the unbalanced pressure on the liquor entering the tube is reduced. The foam formed in the bottom part of the tube rushes up through the hot tube, and part of the fluid in the films is evaporated, thus increasing the relative amount of vapor and decreasing the amount of fluid. A point is reached where the volume of vapor is so great as compared with the volume of the remaining liquor that this liquor can no longer stretch as a continuous film about the vapor, and its separation may be accomplished. There is an all-too-common fallacy that increasing the height of the steam dome over a foamy liquor will decrease the foam. It cannot be done in this way, and a little consideration of the principles involved will convince the most skeptical of the fact. If the height of the liquor in the evaporator is increased the volume of the bubbles is decreased by the static pressure, according to Boyle's law, which, as the temperature is constant, may be written $PV = C$, where P is the pressure, V is the volume, and C is a constant. Then the volume of the bubbles is inversely proportional to the absolute pressure. If the static head is sufficient, the heat transmitted through the tubes may be absorbed in the liquid at a low zone without the liberation of vapor. As the liquid travels upward the static pressure becomes less, until at a certain point vapor can be liberated; this vapor constantly increases in volume until the surface is reached. It is evident from the above that increasing the height of the dome above the heating surface only changes the zone of the foam but not its quantity.

The height of the liquor above the tubes may in some cases be a very important and in some cases a controlling factor. For example, let us consider a case in which the liquor reaches a state of saturation for one ingredient long before the desired concentration of another ingredient is obtained. Such an example might be, for instance, the concentration of a solution containing both caustic soda and sodium chloride. Here, as evaporation proceeds, salt is precipitated, while the caustic soda remains in solution. Now, these sharp crystals of salt at a high velocity exert an abrasive action on the tubes.

Chart 7 is submitted principally for the purpose of illustrating this point. The conditions assumed for the calculations of this chart are: the evaporation of water alone under a vacuum of 6.35 in. mercury, boiling taking place at 212 deg. under 7.5 ft. static head, diameter of tubes 2 in., length of tubes 7 ft., thermal coefficient chosen more or less arbitrarily as 300 B.t.u. per square foot per degree Fahrenheit, average temperature difference of exchange 10 deg. Fahr. No account is taken of the increase in conductivity due to increased velocity.

An examination of this graphic shows that so long as the static head is sufficient to keep the heat in the water instead of forming steam there is no change in the velocity of the liquor in the tube, viz.: with a static head above the tubes of 7.5 ft. of water the velocity is about 0.65 ft. per second, and this is the same for 8.5 ft. static head of water. If, however, there is a static head of only 1 ft., the velocity of liquor entering the tubes is 7 ft. per second, and the velocity of the mixture of steam and liquor leaving the tubes 10 ft. 4 in. per second. Now, let us apply this to the caustic soda illustration, remembering that this chart is only illustrative of water, and that the values would be different for caustic soda, but that the underlying principles are the same.

Where heat is transmitted to the caustic, but steam is not formed, the salt remains in solution, and it is only upon the transformation of the water into steam that the salt is deposited. If this transformation takes place in the tube, the salt is deposited in the tube, and at the high velocity shown exerts an abrasive action on the tube which increases toward the top of the tube owing to the increased velocity. This velocity may, in some cases, reach the proportions of a continued explosion.

In the other case, where the liquor is not transformed into steam in the tubes, it circulates upward until finally as the static head is reduced to the limiting value steam is liberated above the level of the tubes entirely and the salt is deposited where there are no tubes to cut out. Now, much of this salt can be settled out, and what remains travels through the tubes at such a low velocity that it has no cutting action.

The writer has seen many tubes cut off at the top due to the explosive action of steam and salt, while the middle and bottom of the same tubes would show only the slightest wear.

Compare Chart 8 with Chart 7. The only difference in the conditions is that in Chart 8 the tubes are 4 in. in diameter instead of 2 in. The effect of decreasing the velocity is apparent, and needs no further comment.

The shape or surface of the tube may, in some cases, be the controlling factor. Thus, if a corrugated tube is compared with a smooth tube of the same size and of

*A paper read at the St Louis meeting of the American Institute of Chemical Engineers, December 7, 1917.

the same material, it will be found that at low velocities the thermal coefficient of the corrugated tube is greater than that of the smooth tube. At high velocities the reverse is the case. With the corrugated tube the maximum thermal coefficient is reached quickly, and at higher velocities may remain constant or even drop. While the writer's data on this point is, unfortunately, not complete enough to warrant graphical presentation, he has never yet found such a maximum conductivity in a smooth tube.

Calculation of Temperature Differences

In the design of evaporators one of the necessary factors employed in the calculation is the mean temperature difference. Chart 9 shows graphically the varying conditions one may have. Fig. 1 shows a condition where there is a hot medium imparting heat to a cold medium flowing either direct or counter current, and yet no change in the temperature of either. In other words, the temperature difference at any point in the flow is equal to the mean difference. An example of such a condition would be found when one had melting ice in contact with one side of a partition and saturated steam on the other side.

Figs. 2 and 3 are examples in which the temperatures of the media change, but the temperature difference remains constant. A concrete example would be a counter-current exchanger in which the hot liquid entered at 80 deg. and left at 60 deg., and the cold liquid entered at 40 deg. and left at 60 deg. In all of the above cases it is a very simple matter to get the mean

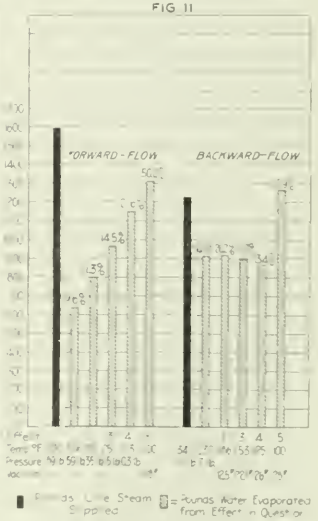

FIG. 16

temperature difference. But in the case of Fig. 4, when the cooler medium is at constant temperature and the warmer medium changes in temperature, as in the example of hot water being cooled by ice or a liquid at boiling point, the mean temperature difference can only be determined in a more complicated manner.

Fig. 5 shows a counter-current conduction example in which the temperature of one medium changes faster than that of the other; such, for instance, as would be the case if the specific heats were different, or if the volumes flowing in unit time were different.

Fig. 6 applies to a parallel-flow exchanger in which the conditions might be as above, with the exception that the fluids flow in the same direction.

Fig. 7 applies to a case in which one fluid changes in temperature by receiving heat from another which does not change in temperature. Such an example would be heating water with steam.

Hausbrand has already developed this subject at some length in his admirable treatise entitled "Evaporation, Condensing, and Cooling Apparatus"; and so it need not be repeated here. Hausbrand has, however, made the subject appear more complex than it really is. Chart 9 is simply Hausbrand's formula simplified. If (a) is the greater temperature difference of exchange and (b) the lesser temperature difference of exchange, then the true mean difference, commonly called the "logarithmic mean," (Lm), may be found by the formula

$$Lm = \frac{a - b}{\log_e \frac{a}{b}}$$

This formula would, of course, not be used for the simple cases of Figs. 1, 2 and 3, of Chart 9. The logarithmic mean in the other cases may vary from the arithmetical mean by amounts ranging from zero to more than 25 per cent, depending on the ratio of the lesser difference of exchange to the greater difference of exchange.[1]

Types of Multiple-Effect Evaporation

We have mentioned herein in a general way the conditions which more or less determine the type of evaporation which shall be followed in a given case. We have not, however, taken into account the fact that there may be varying conditions in the same type of evaporation. In multiple-effect evaporation, for instance, we may follow two distinct and separate procedures.

They are first, forward-flow, the arrangement in which the liquor and steam enter the first effect and the resulting vapor, condensed steam and stronger liquor go toward the last effect; second, backward-flow, or counter-current flow, in which the steam enters the first effect and the resultant vapors and drip flow toward the last effect, while the liquor enters the last effect and is pumped from effect to effect until it emerges concentrated from the first.

In the following illustrative charts the results are only correct to the limit of slide rule accuracy. No allowance has been made for loss of heat by radiation, inasmuch as the amount of this loss can be practically eliminated, if one wishes to do so, by putting on a sufficient insulating covering of the right character. The value of the charts will be found in comparison, and as we have several variables to consider, effort is made to illustrate them in order.

Forward-Flow and Backward-Flow

Suppose we have a solution weighing 5854 pounds, containing 8.54 per cent, or 500 pounds, of solids which have a specific heat 0.5. The liquor enters the system at 32 deg. and we are allowed 20 deg. difference of temperature exchange in each effect. The problem is to concentrate this weak liquor to a 50 per cent solution in six effects. In order to study, as far as possible, one variable at a time, let us assume in this problem that concentration does not materially raise the boiling point. Chart 10 shows that to evaporate this liquor, starting at 32 deg. Fahr., by the forward-flow method, approximately 1490 pounds of live steam are required from the boiler as against 1000 pounds of live steam required by the backward-flow or counter-current method. The next feature to be noticed is that while by the forward-flow method the evaporation increases as the pressure diminishes from effect to effect, in the backward or counter-current flow the evaporation diminishes as the pressure diminishes. In either case the temperature and pressures are the same. In the forward-flow method there is the loss of heat in the extra 490 pounds of condensed steam at 120 deg., equivalent to 43,120 B.t.u., and the loss of heat in the additional 590 pounds of steam at 190 deg. Fahr., equivalent to 651,960 B.t.u., which is lost to the condenser from the last effect. It will be seen that the great loss in heat in the forward-flow is through the condenser; in backward-flow operation much of this heat is utilized in heating up the liquor. In forward-flow operation the cold liquor, instead of being heated by waste heat, so to speak, is heated by live steam.

In the foregoing problem we have assumed that the liquor enters at 32 deg. Fahr. Chart 11 shows the calculated results of a problem in every way identical with the first, with the exception that the liquor enters at 160 deg. Fahr. instead of 32 deg. Fahr. In this case we find that it is more economical of steam to use forward evaporation. Forward evaporation requires 786 pounds of live steam, while backward or counter-current evaporation requires 882 pounds of live steam. Here there is a direct economy of steam in the forward method, to say nothing of the elimination of the necessity of pumping the liquor backward from effect to effect. In forward evaporation the amount of steam saved is not only that which would have been necessary to heat the liquor from 32 deg. to 160 deg., but also the additional saving due to losing less heat in the drip, *i.e.*, as the additional steam required in the other case, after being condensed, carried away a large amount of heat, the saving of this steam also saves this waste. If, however, the evaporation is backward, this heat is lost through the condenser in the steam from the last effect. As we are considering a six-effect system, the saving of live steam by forward-flow operation will be roughly one-sixth of the steam lost through the condenser plus the corresponding saving in the drip.

Having now briefly considered a liquor the concentration of which causes no material rise in the boiling point, let us consider a lquor in which the boiling point

[1]Since writing the above, I find in the November number of the *Journal of American Society of Mechanical Engineers*, a very interesting article by Howard M. Ingham on this subject. He shows an ingenious method of finding the logarithmic mean graphically.

rises markedly on concentration. Chart 12 shows the boiling points of solutions of caustic potash at different concentrations, and Chart 13 illustrates the evaporation of 5854 pounds of an 8.54 per cent caustic potash solution to a 50 per cent solution. In these calculations the specific heat of the caustic potash is taken as 0.5, as in the preceding problems, not because that is correct, but in order not to introduce another variable. This small error makes no fundamental change in the chart. It will be seen that in Chart 13 there are all the general characteristics of Chart 10. The input of steam in forward evaporation has increased nearly 25.5 per cent, while the input for backward evaporation has increased only 6.5 per cent. In forward evaporation the output of steam to the condenser has increased nearly 4.6 per cent, while with backward evaporation it has increased 3.8 per cent. Here, then, there is a large difference in steam input and very little difference in the steam output to the condenser. It will be readily seen from these charts that this difference is mostly due to the increased temperature of the final condensed steam, and the resultant theft of heat.

Temperature Differences

A study of this chart will also show that the other losses of heat in forward evaporation are greater than in backward evaporation. It is not within the scope of this paper to go into the losses of heat by convection to the air, so I will simply confine myself to comparisons, with the general statement that the greater the difference of temperature between similar bodies and the surrounding air the greater will be the loss of heat by convection.

The temperature of the live steam space with forward evaporation is 284 deg., while that of the corresponding space in backward evaporation is 287 deg., a difference of 3 deg. in favor of the former. The temperature of the liquor spaces are 264 deg and 267 deg. respectively, still a difference of 3 deg. in favor of the former. The temperatures of the steam domes are 263 deg. and 218 deg., a difference of 45 deg. in favor of backward evaporation. In the steam spaces of the second effects we have the same temperatures as in the steam dome of the first effects, with a consequent difference of temperature of 45 deg. Table A embodies these comparisons for the whole six effects. It will be seen from the table that there is a total of 6 deg. in favor of forward evaporation and 750 deg. in favor of backward evaporation, or net 744 deg. in favor of the backward evaporation, an average of more than 40 deg. between corresponding effects.

Pressure Differences

Now, as the temperature controls the pressure, it is perfectly logical to place on the same chart the corresponding pressures. While giving the columns of corresponding pressures, it will be noticed that the column of differences is omitted. The reason is obvious. Whereas a substantial excess of pressure on the liquor over that of the atmosphere may be the determining factor as to whether an evaporator can be run efficiently or not, a difference of vacuum practically makes no difference as far as the mechanical operation is concerned. Thus, suppose we had a solution of caustic potash and potassium chloride; a pressure on the caustic effluent might so fill the discharge nozzles with salt, due to the rapid formation of steam at atmospheric pressure, that the operation would not be feasible because of the danger of accidents.

The successful operation of most evaporators requires the use of one or more peep-hole glasses in order that the attendant may be able to watch for foaming tendencies, etc. Now, these sight-glasses, if they are under pressure may either break or crack, and the liquor may blow out into the operator's eyes; there is also the theoretical possibility of the glass itself blowing into his eyes. If, however, a vacuum is maintained, any such breaking or cracking of glass will be inward and the direction of the fluid will be away from the eyes and not toward the eyes.

A = Heating-steam Space.
B = Liquor Space.
C = Evaporated Steam Space.

In the above caustic potash example, owing to the flatness of the boiling-point curve at the lower concentrations, nothing has been said about the heat of chemical combination with water, or heat of dilution, though this factor was considered in making the calculations. The effect is small, however, so that it does not materially affect the elements of the chart. The object sought was to show the results which must follow an increase in the boiling point during concentration.

Heat of Combination with Water

Let us now consider the effect of the heat of chemical combination of the solids with water. Unfortunately there does not seem to be any good illustration of a case in which there is not a perceptible change of boiling point also brought about by dilution. However, if the preceding illustrations are well understood, there should be no difficulty in understanding this variable. One calculation could be made neglecting the heat of chemical combination and another taking this factor into consideration, but the first would be so far from the truth that a comparison of the two results would not only be of no value but would actually be misleading.

It is well known that there are many substances which dissolve in water with a marked rise in temperature; such, for instance, are sulphuric acid, hydrochloric acid, ammonia, and caustic soda. Now, it is apparent that

if these substances give up heat when added to water, they must likewise absorb heat when separated from water. If this were not so we should have perpetual motion. Now, the data obtainable on this subject is not in the form which lends itself to the calculation of evaporator problems. The first thing, then, for one to do who has a problem in which the heat of chemical combination is an important factor, is to take his data and reconstitute it so that it shall be in convenient form. This may be done much in the same manner as a civil engineer makes a contour map from data of elevations and distances. He connects all points of equal elevations at whatever distances they may happen to be and one is then able to determine the elevation of any particular point by interpolation between successive contours.

Chart 14 gives the relation of boiling point to concentration of caustic soda solutions and Chart 15 is a "contour map" of the heat of dilution of caustic soda solutions expressed in B.t.u. per pound of water added, concentration being changed between known values. Thus, suppose a 40 per cent caustic solution is to be concentrated to a 50 per cent caustic solution; at the intersection of the ordinate 40 and the abscissa 50 we find that the heat of dilution or vice versa, the "heat of concentration," is 210 B.t.u., for every pound of water so evaporated. Thus, in the heat-balance equation for one evaporator effect there might be an equation like this, where x is the weight of water evaporated in that effect:

$$(1865 - x)\ (161) + 1104x + (5439)\ (181) + 210x = (1865)\ (203) + (4259)\ (224) + 1150x$$

It will be seen that after solving this equation for its unknown, the actual amount of "heat of concentration" required may be calculated.

Now, in order that we may see the effects of heat of chemical combination and rise in boiling-temperature combined, let us examine Chart 16. The forward-flow operation is an impossible case as far as practice is concerned, on account of the high pressures we have to contend with. This chart shows the conditions encountered in evaporating an 8.54 per cent caustic soda solution at an original temperature of 160 deg. Fahr., to a 50 per cent solution. It will be seen that in effect No. 2 backward-flow operation, the liberation of steam is greater than in effect No. 1. Heretofore we have had no such abrupt changes. Let us see how this happens. In effect No. 1 there is a high heat of chemical combination, all of which heat is furnished by the latent heat of the live steam, and consequently the steam liberated will be very much less than it would be if there were only a low heat of chemical combination. In the second effect, however, there is a large quantity of condensed steam from the first, cooling approximately 93 deg. This liberates heat enough to raise the evaporation of steam in that effect above the abnormally low value of the first effect. Referring to Chart 15, it will be seen that the heat of combination between 26.1 per cent and 50 per cent concentration is 109 B.t.u. per pound of water evaporated. This same condition applies to forward-flow, but is not so noticeable (see Effect 5), first, because of the large increase in evaporation from effect to effect; second, because the concentration is in that case between the values 21.6 per cent and 50 per cent, instead of between 26.1 per cent and 50 per cent. If, however, the differences are subtracted and the results compared with the preceding charts, the effect of this property will be apparent.

In Chart 11 it was demonstrated that the forward-flow method was more economical of steam when the liquor to be evaporated had been preheated to a considerable extent, viz., 160 deg., in this illustration. But it does not follow that because this is true of liquids in which concentration does not materially raise the boiling point that it is true for those liquids which increase markedly in boiling point on concentration. Thus, Chart 16 shows that backward-flow evaporation is decidedly more economical in steam than the forward method for caustic soda. Here it will be seen that the loss of heat in the drip, due to its high temperature, more than offsets the extra heat lost through the condenser in backward-flow.

Chart 17 is submitted showing the evaporation of the same caustic soda liquor with the conditions the same except that the liquor enters at 32 deg. Here the same rise in evaporation in No. 2 effect backward-flow is

FIG. 19

apparent, and the decrease in evaporation of No. 5 effect in forward evaporation is equally apparent; as before, the abnormalities are due to the large heat of chemical combination at these points.

In the two last charts the effect of the heat of chemical combination has been illustrated, using a caustic soda solution as an example. In this case the heats of chemical combination are positive. It might be interesting to take an example such as the concentration of ammonium nitrate, in which the heats of dilution with water are negative. The time at the writer's disposal does not permit of his making the necessary charts or calculations, however, and, moreover, we have already considered the subject of heat of chemical combination as fully as it justifiable in a general paper.

Usefulness of the Charts

A study of the charts already submitted will show that not only do they give an idea of the consumption of steam and the mechanical strength required, but that by calculating a chart for the problem in hand one can save in first cost of equipment. For instance, in Chart 16, the condenser for backward-flow operation could not be much smaller than in forward-flow, though the boiler might be smaller. This chart also shows that the piping into the condenser in each case would be nearer the same size. Also, inasmuch as the amount of steam to be condensed is very nearly the same, the amount of water to be handled is much the same.

Comparing the two divisions of Chart 17, one will see that the boiler has to be approximately 70 per cent larger for forward evaporation than for backward evaporation. The condenser in the former has to possess 90 per cent greater capacity than in the latter, and the water supply and equipment must also be greater. The question of water supply alone might decide one in favor of the backward-flow type of evaporation.

Another fact to be observed is that in the backward-flow process the intermediate piping can, as a rule, be approximately of uniform size without waste, while such is not true of the forward-flow method. The former method lends itself better to standardization.

A further study of the subject will show that in the forward-flow method, to a much greater degree than in the backward-flow method, adding an additional effect does not give a proportionate economy of evaporation, and that interest on the investment and maintenance charges may more than offset the economy gained.

Temperature Difference of Exchange

In the foregoing illustrations the temperature difference of 20 deg. Fahr. has been used in each instance. This has been done in order that the point which we wish to consider shall not be obscured by greater variations. It is not, however, meant to intimate that evaporation is always done under 20 deg. difference of exchange, or that 20 deg. is preferable to 10 deg. or 25 deg. The writer is familiar with an evaporator in which the following are the approximate differences of exchange: 8 deg., 9 deg., 15 deg., 20 deg., 26 deg. and 70 deg. This is due to the increase in viscosity of the liquor.

Where a liquor tends to decompose or "gum up" on concentration at high temperatures, and becomes viscous at low temperatures, there is still another procedure which can be followed. Suppose the travel of the liquor is as follows, the effects being numbered serially: 6, 5, 4, 2, 1, 3. Here the liquor gives up its last water at a temperature high enough so that it will remain mobile. A large number of these combinations might be made, and the subject is of enough importance to warrant investigations along this line. The experimental data available at present is not sufficient to warrant submitting many calculations. We have, however, gone far enough in certain experiments to lead us to believe that in spite of the extra complications this method will be useful under certain unusual conditions.

Chart 18 shows that in comparison liquor evaporated backward in the order 6, 5, 4, 3, 2, 1 and backward in the order 6, 5, 4, 2, 1, 3, all the other conditions are alike. It will be seen that the steam consumption is the same in each case, but this is only a coincidence and would vary if the order was changed, the difference of exchange, etc., etc. The coincidence in this case is brought about by recovering some of the heat of the liquor at high temperature from No. 1, which increases the evaporation in 3, 4, 5 and 6, thereby making up for the loss of the decreased evaporation in 1 and 2. It is interesting to note the high evaporation in No. 3, which is due to not having to raise the entering liquor 20 deg., and also due to the giving up of steam by the liquor from No. 1 as in forward evaporation.

If liquor is to be sprayed into a furnace to be evaporated by radiant heat, as described in a previous paper by the author, this backward method, viz., 6, 5, 4, 2, 1, 3, has decided advantages, as the liquor goes in at 160 deg. F. instead of 100 deg. F.

As the thermal coefficient increases with the velocity of the liquor (and therefore also with its mobility) it will be readily seen that by increasing the velocity (or mobility) the heating surface required can be reduced.

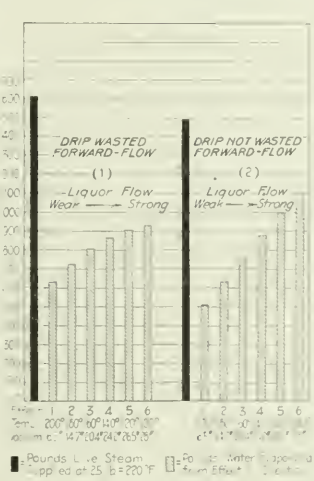

FIG. 20

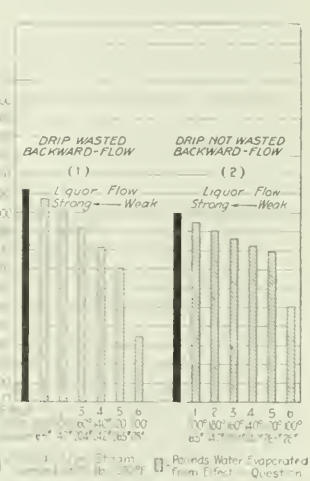

FIG. 21

The velocity or mobility of the liquor is not, however, the only thing to be considered in designing the heating surface of multiple effect evaporators. If air accumulates in the steam space, the effect is the same as reducing the heating surface. It has been assumed for lack of better knowledge on the subject that this effect is in direct proportion to the per cent by volume of air present and the evaporator designer will not go very far wrong if he goes by this rule. The accumulations of air in only one effect may stop the operation of every evaporator in a multiple-effect system. It will thus be seen that evaporators should be so designed that the inlet and outlet for air and its accompanying steam will be so located as to prevent air pockets.

Drip from Evaporators

Many manufacturers waste the condensed steam, that is, they remove the "drip" of each effect separately, and do not try to obtain the available heat therein. This in some cases is justified, though as a general practice the principle is unsound. A justifiable use is in the case of foamy materials where the liquor may be expected to foam over without warning. In this case, if the drips are kept separate, only a portion of the drip liquor would have to be re-evaporated in case of accident, instead of the whole. The efficiency, however, is not as great as when the drip is carried from one effect to another. If the saving due to less re-evaporation is greater than the saving in steam, the method is justifiable. Chart 19 shows the effect on the steam consumption in both forward and backward evaporation by wasting the drip from each effect.

The comparison is more striking if we compare the forward flow with forward flow in Chart 10, and backward flow with backward flow in Chart 10.

Charts 20 and 21 show this comparison, and in the case given for forward evaporation requires 5.6 per cent more steam, and for backward evaporation 12.2 per cent more steam. It is also interesting to note how the wasting of the drip changes the relative evaporations from effect to effect.

This paper does not pretend to go into the matter of steam consumption, the utilization of waste heat in steam to condenser, in drip and hot liquor. Much of this heat can be profitably saved, but as this is not a paper on heat utilization, but on evaporation, this phase will be passed over.

Multiple-effect evaporators should be connected with by-pass valves, so that any effect may be repaired while the others are running.

In conclusion, the writer wishes to express his hope that this paper may suggest subjects for a full discussion, by which means he is sure matters of the greatest interest and profit to the Society may be brought out. He also wishes to acknowledge valued assistance rendered by Mr. W. B. Van Arsdel in the preparation of the material presented.

Brown Co.
Berlin, N. H.

No Spring Meeting for American Chemical Society.—The directors have voted to omit the Spring meeting of the society, which was to have been held in St. Louis the coming April. It was felt that the transportation conditions are such that unnecessary travel should be avoided, and also that the chemists of the country are too busily engaged in meeting war needs.

The Physical Properties of Copper and the Factors by Which They Are Affected*—II

By Paul D. Merica
Division of Metallurgy, U. S. Bureau of Standards

(*Continued from page* 127)

4. Mechanical Properties

In any discussion of the mechanical properties of any material, it must constantly be borne in mind that most of the characteristics determined are more or less dependent upon the method of their determination; the size and shape of test-piece used, the rate of loading, etc., as well as upon the previous mechanical and heat treatment of the material. This is much less true of the elastic properties, the moduli, etc. In general, therefore, it is not possible to assign definite values to these mechanical characteristics; only the range of values given by pure material treated in different ways can be given.

Martens, in an article of great value to those interested in the testing of copper (140), has shown that in the case of copper a variation of testing speed amounting to from 0.5 per cent to 40 per cent elongation per minute causes a difference in the value of the ultimate tensile strength of less than 2 per cent.

Ludwik (139) has, however, shown that for longer periods, the effect of time in testing is quite large. He found that a ½-mm. diameter electrolytic copper wire which sustained a load of 4958 grams for 5 minutes sustained a load of only 4500 grams for 90 hours and one of 3950 grams for 1¼ years.

Martens also showed that although the form of the test piece—ratio of test length to cross section, distance of test length from shoulder of test specimen, etc.—had practically no effect on the values of the ultimate strength and yield point of copper, it exerted a marked effect on the elongation and reduction of area in the tensile test; variations of 15 to 30 per cent were obtained on the same material by varying the ratio

$$\frac{\text{length}}{\text{cross section}} \text{ from } 1/20 \text{ to } \tfrac{1}{2}.$$

(*a*) *Elasticity.*—There is some divergence among the results of determinations of Young's modulus for copper. Values of from 12,100 to 12,300 kg./mm.^{2} (17.2 to 17.5 $\times$ 10^6 lb./sq. in.) have been obtained by careful investigators for electrolytic copper. Determinations by Searle (121) showed a value of 17.6 $\times$ 10^6 lb./sq. in. for drawn and of 18.3 $\times$ 10^6 lb./sq. in. for annealed copper. The temperature coefficient of E at ordinary temperature for copper is given by Wassmuth (125) as $\alpha = 3.59 \times 10^{-4}[E = F(1 + \alpha t)]$ and is negative, *i.e.*, the modulus decreases with rise of temperature. Some values for the moduli at different temperatures are given in Table II.

Poisson's ratio for copper is 0.33 ± 0.01; its temperature coefficient (0 deg. to 150 deg. C.) about 0.00023.

The modulus of torsion for copper as given by Koch and Dannecker (124) is 4240 kg./mm.^{2} (6.15 $\times$ 10^6 lb./sq. in.).

[1], [2] determinations on different samples of copper

The modulus of hydrostatic compression for copper is approximately 12,000 kg./mm.² (20).

(*b*) *Tension test.*—Pure copper may be best normalized by casting, rolling and drawing, followed by annealing for one-half to one hour at about 500 deg. C. and then by slow or quick cooling; after this treatment there is less variation between different samples in the results of the tensile test than in any other condition. The tensile characteristics of copper in this state may be summarized as follows:

Ultimate tensile strength, 35,000 ± 5000 lb./sq.in.
Elastic or proportional limit not determinable.
Elongation in 2 in., 40 to 60 per cent.
Reduction of area, 40 to 60 per cent.

It will be noted that no value is given for the elastic or proportional limits; the usual method of determination of these quantities does not yield any value; *i. e.*, annealed copper yields slightly with the slightest loads which are applied in testing. The values of the moduli given above are determined generally on hot rolled material in which a practical proportionality exists for very small loads.

When copper is cold-worked, rolled or drawn, the

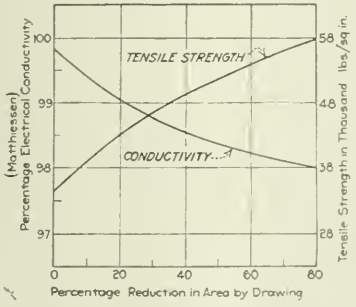

FIG. 15. EFFECT OF COLD WORK ON ULTIMATE TENSILE STRENGTH AND ELECTRICAL CONDUCTIVITY OF PURE COPPER (ADDICKS, 184)

The ultimate tensile strength and the per cent electrical conductivity are plotted as a function of the per cent reduction (area). The wires tested were drawn to No. 12 B. & S. gage from different sizes of annealed copper rod

hardness and ductility are increased and decreased respectively; at the same time a limit of proportionality makes its appearance. The hardness and ductility of such material depends on the amount of cold work or reduction (rolling or drawing) it has received. Figs. 15 and 16 give a good idea of the changes in these quantities in copper strips with various degrees of cold reduction.

Experiments made at this bureau have shown that modern hard-drawn copper wire is equally affected by drawing throughout the section, and that no hard or exterior skin exists. This has been corroborated by Peirce (141).

A good indication of what tensile test values are to be expected in commercial copper wire, hard, medium,

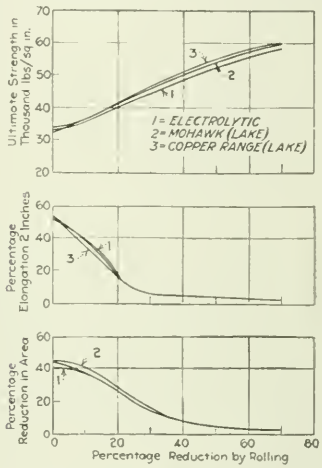

FIG. 16. THE EFFECT OF COLD WORK ON THE MECHANICAL PROPERTIES OF COPPER (TENSILE TEST). (MATTHEWSON & THALHEIMER, 191)

There are plotted the ultimate tensile strength, the elongation in 2-in. and the reduction of area for copper strips rolled to different gages from an annealed strip 0.128 in. in thickness as functions of the percentage reduction of area.

	Per Cent Oxygen	Per Cent Arsenic	Per Cent Silver

Curve 3. Copper Range copper (Lake arsenical	.055	.296	.052

drawn and soft may be obtained from the American Society for Testing Materials Specifications.

By increasing the current density and employing a rapidly rotating cathode, Bennet (133) has been able to produce electro-deposited copper of a hardness approaching that of hard-drawn copper; *i. e.*, of a tensile strength of 68,000 lb./sq. in. Some experiments indicating the effect of varying current density upon the mechanical properties of copper were earlier obtained by Von Hüble (137).

Thurston (147) and others give values of the results of the tensile test on copper in different conditions.

TENSILE TEST

Material	Ultimate Strength, Lb./Sq. In.
Cast copper	22–36,000
Copper, forged	34,000
Copper, bolt	36,000
Copper, sheet	36,000
Copper, wire	62,000

(*c*) *Compression Test.*—Copper of good quality does not fail in the compression test by fracture, it merely yields indefinitely and becomes flattened out.

Thurston (147) states that the resistance of copper

to compression may be calculated (within the limits $e < \frac{1}{2}$) from the formula

$$c = 145{,}000 \sqrt[3]{e}$$

c = resistance in lb./sq. in. of original area

e = fractional compression

This formula holds, according to him, for compressions up to 50 per cent for cylinders of three diameters' length.

(*d*) *Torsion Test.*—Thurston (147) states that copper shafts will break under load when

$$d' = \sqrt[3]{\frac{Fl}{4000}} \text{ or } d' = \sqrt[3]{\frac{Fl}{8000}}$$

according as they are of cast or worked copper.

d' = diameter in inches

F = torsional moment

l = lever arm

He also gives the equation

$$d' = \sqrt[3]{\frac{5.1\,Fl}{S'}}$$

where S' for copper should be from 15,000 to 30,000 lb.

(*e*) *Shear Test.*—The shearing stresses for copper are given in the *Ordnance Manual* of the United States War Department. The shearing resistance of copper may be taken (Thurston, 147) as equal to that of the ultimate strength in tension and subject to the same variations; *i. e.*, in the annealed or cast condition, 22,000 to 36,000 lb./sq. in. The work done in shearing copper (for punched holes) is (147)

$W = 96{,}000\,dt$

W = work in foot pounds

d = diameter of hole

t = thickness of plate or sheet

(*f*) *Transverse Bending Test.*—Thurston (147) gives the modulus of rupture as varying between 20,000 and 40,000 lb./sq. in.

(*g*) *Hardness Test.*—It is well known that this property is expressed in many different ways, many of them quite arbitrary.

On the Mohs or mineralogic scale copper has a hardness of from 2.5 to 3. Tammann (146) states that soft and hard copper gave the same values of sclerometer hardness. A hardened steel needle (Martens sclerometer) gave a scratch of 0.014 to 0.016 mm. width when loaded with 10 grams, and one of 0.022 to 0.027 mm. when loaded with 17 grams.

The scleroscope hardness of annealed copper varies from 6 to 7 (universal hammer), whereas that of hard copper (cold reduction of 66 per cent) varies from 22 to 24 (186).

The Brinell hardness of annealed or cast copper is 35 ± 5 (500-kg. load, 10-mm. ball); when hardened by cold work the ball hardness thus defined may become as high as 100. Guillet (189) has determined the ball hardness and the tensile strength of copper in various states of hardness, produced by pressing annealed copper in a steel die to different thicknesses. His results are given in Table III.

Table III—Brinell Hardness of Copper

Per Cent Cold Reduction of Section	Brinell Hardness Numeral, 500 Kg.		Tensile Strength, Lb./Sq. In.	Elongation in 11 Cm. per Cent.
	10 Mm. Ball	5 Mm. Ball		
Annealed 0.....	42	50	33 600	46
10.....	70	74	36 000	24
20.....	81	81	40 000	13
30.....	86	90	45 000	5
40.....	94	92	47 800	4.5
50.....	96	95	52 600	4.2

It is seen that that ratio of $\frac{\text{tensile strength}}{\text{Brinell hardness}}$ is variable with the hardness of the copper.

(*h*) *Impact Test.*—Impact tests of copper have been so few that no final or typical values could be chosen from the data. Baucke (132) has carried out a number of tests according to Frémont, using rectangular bars 10 x 10 mm., with a sharp saw-notch of 3 mm. depth; the specific impact work was measured. Some of the results are given in Table IV. He compares the tensile strength, reduction of area and elongation (in (?) in.). For certain special brands carrying arsenic, nickel and iron (98.5 to 99.9 per cent copper), giving tensile strengths of from 20 to 31 kg./mm.^{2} (28,400 to 44,000 lb. / sq. in.), elongations of from 40 to 50 per cent, reductions of area of from 50 to 77 per cent, the specific impact work varied from 10 to 33 kg. M. (72.4 to 239 ft. lb.) in longitudinally cut specimens and from 9 to 31 in transverse specimens. For ordinary brands, oxygen content 0.11 to 0.06 per cent, copper 99.5 to 99.8 per cent, having tensile strengths of from 21 to 24 kg. mm.^{2} (30,000 to 34,000 lb. / sq. in.), elongations of from 30 to 47 per cent, reductions of area from 33 to 70 per cent, the specific impact work varied from 10 to 15 kgM. (72.4 to 109 ft. lb.) in longitudinally cut specimens and from 3 to 11 kgM. (21.6 to 79.5 ft. lb.) in transverse specimens.

(1)—Baucke gives S. I. W. in kilos, but it is assumed that he means kilogram-meters.
L = longitudinally-taken specimens.
T = transversely-taken specimens.

5. Miscellaneous

(*a*) *Density.*—The density of pure copper, rolled, forged or drawn and afterward annealed, may be taken as 8.89 at 20 deg. C. This value was accepted by the

International Electrotechnical Commission in 1913. Samples of high conductivity copper will vary (149) usually between 8.87 and 8.91; in some cases samples have shown densities as high at 8.94 and as low as 8.83. Variations in density may be due to microscopic flaws or seams (low density) or to the variation in the percentage of oxygen present (0.03 per cent oxygen lowers the density by about 0.01). The density of cast copper will be about 8.89 when no blowholes are present; otherwise lower densities will be found.

According to experiments by G. L. Heath (148) there is but an extremely small difference between the density of hard-drawn and hard-drawn annealed copper. No difference in density is detected between the two high grades of copper. The mean density of 10 hard-drawn samples of wire was 8.898; after these samples had been annealed their mean density was 8.900, showing an increase of density upon annealing of approximately 0.02 per cent. Similar values of the increase in density of hard copper upon annealing have been found also by Gewecke (187) and by Kahlbaum-Sturm (150); these ranged from 0.001 to 0.10 per cent, and averaged about 0.02 per cent.

(To be Continued)

Intensive Toluol Production—II.

Proposed Improvements in the Concentrating and Refining Process

By Frank E. Lichtenthaeler

CRUDE light oil containing benzol, toluol and other less important constituents is obtained by subjecting the vapor-gas mixtures of these substances to the absorbing action of a higher boiling medium, with subsequent heat treatment of the absorbing medium to remove the recovered volatile portion. This is commonly known as the absorbing and stripping process for toluol recovery. In a previous article[1] dealing with this process we have recommended the use of tar as the most suitable absorbing medium, at the same time offering improved procedure and plant, broadly conceived, in the hope of contributing toward a quick and permanent relief of the existing critical situation in respect to the deplorably short supply of toluol.

Present Concentrating and Refining Process

The usually accepted method of working up the crude light oil to produce "toluol pure" has been described at length in other publications, of which the recent and interesting report of the United States Bureau of Standards is mentioned in the way of reference. The crude light oil is roughly separated by distillation into three fractions, known as crude benzol, crude toluol and crude solvent naphtha, by means of a periodic still having a short rectifying column. The crude toluol fraction is treated chemically with sulphuric acid to remove olefines and other unsaturated bodies, washed with water, neutralized with dilute alkali solution and again washed with water to remove any excess of alkali. The olefine-free toluol fraction is finally distilled in a periodic rectifying still, using a tall column of standard bell-and-seal type with external reflux condenser or dephlegmator. In the latter operation the finished toluol-pure fraction constitutes the middle portion or heart of the run. These related operations, or their equivalent, we have termed the concentrating and refining process.

Evolution of Present Procedure

In the hope of developing a better perspective in regard to the toluol concentrating and refining process, it seems desirable to review briefly the evolution of the above mentioned procedure. Contrary to the older and more highly developed European chemical practice, there has been a marked tendency in America to employ inadequate apparatus for carrying out the initial steps of a process, without realizing that the imperfect result, directly attributable thereto, predetermines the necessity of more elaborate and difficult refining operations at the end. Our synthetic chemical industry is replete with striking illustrations of this fallacious practice, although there are exceptions pointing to real progress due to more logical conceptions and a willingness to make judicious expenditures for well adapted plant for preliminary work in order to simplify succeeding operations.

Naturally, the development of light-oil concentrating and refining has followed a similar channel. Formerly the crude light oil was distilled and redistilled in plain stills, without columns or dephlegmators, and extremely rough concentrations were thus effected. Consequently the tax on the chemical washing operation was heavy and the shrinkage at this point considerable. The rectifying operation was carried out in antiquated types of column stills, the supposed advantage being that they were cheap to build. Two or three distillations were thus required, the excessive and accumulative cost of which long escaped attention. In course of time it occurred to some venturesome innovator to try a fractionating column in connection with the initial distilling operation. The column, if we may dignify it as such, consisted of an upright piece of pipe filled with coke or quartz pebbles. A decided improvement resulted, and all those divining the secret immediately did exactly likewise and profited accordingly. Another lapse of time and the idea suggested by the pebble column again overcame inertia, with the result that the present short cap column and dephlegmator were applied, notwithstanding the radical departure this step involved. The results were surprisingly good, which brings the history to date where progress once more pauses to further demonstrate the fallacy of leaving well enough alone.

Analogous Development of Wood Chemical Practice

The development of the wood chemical industry in America affords an interesting analogy to the above. Crude methods and apparatus have been adhered to with astonishing tenacity worthy of a better cause. Consider for example our time-honored practice of producing 82 per cent crude wood alcohol, yellow with tar, loaded with the most baffling impurities, and requiring elaborate and repeated treatments by distillation and chemicals to eventually yield a semi-refined alcohol. The magic of 82 per cent crude rests solely in the fact that this was the highest concentration attainable with the old-fashioned Burcey pan stills even now in use at some of the plants. This has set the pace for present and future generations, with here and there an isolated exception, notwithstanding the fact that our Canadian neighbors have long since discovered that by continuous concentration of the neutralized wood liquor

[1] This journal, Feb. 1, 1918, pp. 144-152.

in an efficient column still of modern design the tar and oily impurities can be eliminated completely at the start, distilling over a water-white highly concentrated product, which may be sold directly as wood alcohol or very easily refined to pure methyl alcohol 99½ per cent strong containing below one-eighth of 1 per cent of acetone.

This nearly parallel case is referred to as suggesting the desirability of applying to the concentrating and refining of crude light oils certain definite improvements in distillation methods and apparatus which have contributed so much toward better economy in the wood chemical field. A comprehensive system of concentrating and refining volatile liquids by distillation has been developed, based on our experience and observations extending over many years; a system that has been thoroughly and successfully tried out not only in the wood chemical field, but in various other instances, always involving a crude material of complicated composition from which it is desired to isolate one or more volatile components in a highly refined condition. This system has, as its foundation, the premise that the concentrating operation, *i. e.*, the isolation of fractions in which the desired components predominate, by the very character of the work to be performed, demands apparatus of the highest practical efficiency. Thus only can objectionable impurities be removed that otherwise persist as an unnecessary burden through all succeeding operations. Needless labor and operating expense thus eliminated at the start represent a very substantial economy, as compared to the more usual practice, especially in the case where valuable materials are to be handled on an enormous scale. Could there be a more opportune occasion for the application of this obviously more logical and economical procedure than presented by the unsatisfied demands for an unlimited supply of toluol for war and after-war needs?

Other important benefits to be derived from the use of efficient concentrating stills for the preliminary fractionation of crude light oil may be enumerated. Olefines are more completely removed from the principal concentrate, crude toluol, so that the latter requires correspondingly less sulphuric acid in the chemical treatment. Furthermore, these otherwise lost olefines, together with separable paraffines, become readily available for gas enrichment. High concentration obtainable in respect to toluol means less benzol and solvent naphtha to be removed in the final rectifying operation, with consequent higher yield of toluol in one operation. It directly follows that the final rectifying still, having less work to perform, may be correspondingly smaller. The reduced steam consumption alone, due to economies made possible by continuous operation, affords ample justification of the suggested procedure.

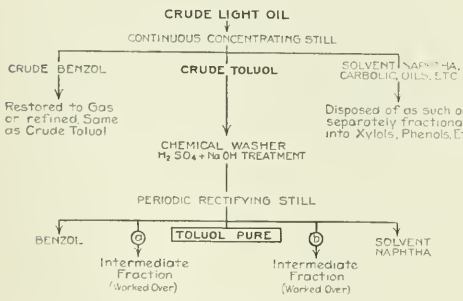

FIG. 7. LUMMUS SYSTEM OF "LIGHT OIL" CONCENTRATING AND REFINING

Light-Oil Concentrating and Refining

The Lummus system of light-oil concentrating and refining, as illustrated diagrammatically in Fig. 7, is described briefly as follows:

The crude light oil is handled directly in an efficient continuous concentrating still, which effects a simultaneous separation into three concentrates, which we will term crude benzol, crude toluol and solvent naphtha. The crude toluol fraction, containing all the toluol present in the original light oil, together with a small percentage of lower and higher boiling impurities, is next treated chemically with sulphuric acid to remove olefines and other unsaturated bodies, washed with water to remove acid left in suspension, then with dilute caustic soda solution to neutralize the remaining traces of acid, and finally again washed with water to remove any excess of caustic soda. The neutral crude toluol is then fractionated in an efficient periodic rectifying still, the following fractions being collected in order of their increasing boiling points: benzol, intermediate fraction *a*, toluol-pure, intermediate fraction *b* and solvent naphtha. Toluol-pure, forming the main part of the run, is here turned out in finished condition, ready for shipment to the munitions factories, and our main purpose is thus accomplished.

Intermediate fractions *a* and *b*, both containing toluol, are run into the same tank and re-distilled after sufficient quantity has been accumulated for a full still charge, using the same periodic rectifying still mentioned above. The combined benzol fractions, resulting from both the continuous and periodic still operations, may be restored to the illuminating gas, or eventually may be used in the manufacture of explosives. Chemical treatment and final rectifying must be applied to this unfinished material to yield benzol-pure. These operations may be carried out in exactly the same manner as described in connection with crude toluol. The same apparatus may be used for producing benzol-pure provided, of course, that sufficient capacity has been furnished with this end in view.

Assuming that tar has been used as the absorbing medium, as suggested in our previous article, the solvent naphtha fractions referred to above would contain carbolic oils as well as xylols. In this case it may ultimately prove desirable to work up the carbolic oils into phenol for picric acid, thus requiring additional apparatus especially designed for the purpose. As this is a separate undertaking from that of producing toluol, we will not stop at this time to describe in detail the methods and apparatus for working up these side products. The solvent naphtha fractions may be subjected to cracking processes and thus caused to yield additional benzol and toluol in substantial amounts. It was first pointed out by Dr. W. F. Rittman that the mixture of higher boiling aromatic compounds constitutes a highly favorable raw material for producing toluol by cracking either in tubes or furnaces, and as recently confirmed and demonstrated in a timely reminder of

this important possibility, some millions of gallons of toluol could thus be added to the supply.

It will be observed that the concentrating and refining process recommended is practically the same as that commonly followed, except that a continuous concentrating still is employed for the preliminary fractionation in place of the short column periodic still usually mentioned. We advocate this radical change

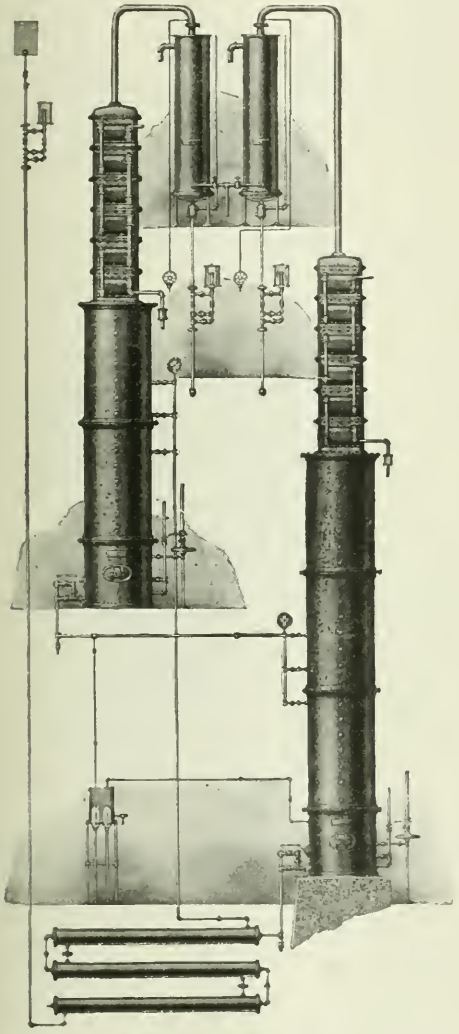

FIG. 8. LUMMUS DOUBLE-COLUMN CONTINUOUS CONCENTRATOR

in order to gain the important advantages referred to in paragraphs six and seven above, none of which is possible with any other type of apparatus. Furthermore, in the final rectifying operation we employ an improved design of fractionating column capable of effecting sharper separations, thus increasing the initial yield of toluol-pure, at the same time materially reducing the quantity of intermediate fractions, which require working over with consequent duplication of expense.

Double Column Continuous Concentrator

The continuous concentrating still, recommended for the preliminary fractionation of the crude light oil, is illustrated in Fig. 8. This is known as the Lummus double-column continuous concentrator, designed for turning out simultaneously the three concentrates mentioned above. This apparatus is of iron construction throughout, and especially adapted to conditions obtaining in the case under consideration. That is to say, while the type of still is one that we have applied broadly to various concentrating problems, the specific apparatus shown is a recent development, designed and proportioned throughout for continuous fractionation of crude light oil into crude benzol, crude toluol and solvent naphtha. Note that both columns include the system of internal refluxing, which, in our opinion, represents the highest development of the art, affording the best means for effecting sharp separations of mixed volatile liquids, with high economy in respect to steam and water consumption. This system will be described more in detail in a later paragraph. Both distilling columns are provided in their bottom chambers with suitable high-pressure steam heating coils and perforated sparger pipes for injecting live steam, although the use of the latter is not always necessary. A heat interchanger is used for economizing the waste heat of the residual solvent naphtha fraction discharged from the bottom of the second column, and ample control of conditions is provided for in the way of column pressure regulators, recording thermometers for charting the boiling points of distillates, dial thermometers for the various feed liquors, feed and product gages for measuring the rate of flow of both feed and distillates, also special testers for checking the liquor discharged from the first into the second column and for indicating the composition of the residual solvent naphtha fraction.

Referring to Fig. 8, the crude light oil flows by gravity into a small constant-head float tank from a suitable elevated storage tank. The rate of flow of the crude light oil, fed continuously to the apparatus, is controlled by a suitable valve and accurately measured by a feed gage, as shown at upper left-hand corner. The crude light oil next is heated in heat interchanger, shown at bottom of cut, by means of the waste heat of the solvent naphtha fraction and is then admitted to column No. 1 through one of the manifolded inlet connections. The temperature of the inflowing feed is indicated by a dial thermometer. The conditions in column No. 1 in respect to the amount of heat supplied and the temperature maintained throughout the internal reflux system are adjusted to cause the vaporization and concentration of the so-called crude benzol fraction. This fraction, comprising benzol and all lower boiling components—but no toluol—is condensed and cooled in a final condenser from which it flows to its storage tank, the rate of flow and boiling point being indicated by a product gage and recording thermometer shown directly below the condenser.

The residual liquor emerges from the bottom chamber of column No. 1 and crosses over to column No. 2,

[3]Egloff, Jour. Ind. & Eng. Chem., Vol. 10, No. 1.

being admitted through one of the manifolded inlet connections at a fixed temperature indicated by a dial thermometer. In this column conditions in respect to heat and internal refluxing are adjusted to effect vaporization and maximum concentration of the crude toluol fraction, which is condensed and cooled in its respective final condenser from which it in turn flows to its storage tank, the rate of flow and boiling point also being indicated by a product gage and recording thermometer, as shown. The crude toluol fraction comprises all of the toluol present in the original crude light oil, together with small percentages of benzol, olefines, paraffins and traces of other components boiling slightly higher than toluol.

The residual liquor, known as solvent naphtha, and comprising components of higher boiling point than toluol, flows from the bottom chamber of the second column through the heat interchanger previously referred to and thence to its storage tank. It will be noted that the three products are turned out simultaneously and at a continuous uniform rate throughout 24 hours of the day. There is no time lost for still charging and dumping, nor for heating and cooling the charge—these being the inherent disadvantages of the present periodic or batch concentrating stills.

Internal Reflux System

A brief description of the Lummus internal reflux system may not be out of place at this point of our discussion, together with a statement of our reasons for applying this system to the concentration of crude light oil fractions. All other continuous or periodic column stills employ what is known as an external reflux condenser or dephlegmator, the purpose of which is to flood the column chambers with condensate of reasonably high purity, this being favorable to increasing the purity of the final vapors passing from the top of the column. Unfortunately, by returning this condensate to the top chamber only, this very desirable effect is largely confined to the few uppermost decks of the column with the direct result that an excessive amount of condensate must be returned, which requires a correspondingly excessive amount of steam for re-evaporation, as well as water for condensation. The Lummus patented internal reflux system consists of a number of small reflux condensers or dephlegmators distributed throughout the entire upper part of the column, so that each tray of bells and seals is provided with its individual dephlegmator. By thus distributing the work of refluxing, not only are much sharper fractionations made possible, but this may be accomplished with very much less steam and condenser water. The requisite column construction, although slightly more elaborate than that applying to the externally placed dephlegmator, is eminently practical, and after sixteen years of development has naturally been reduced to routine practice with us, so that the ultimate cost is practically the same as that applying to the somewhat more simple though far less efficient external dephlegmator. The several water-cooled tube bundles, constituting our internal reflux system, are all removable intact for cleaning, testing and replacement of worn out tubes. In fact, this type of apparatus is far more accessible than the less modern external dephlegmator, while so far as operation is concerned, adjustment and control of conditions are accomplished more conveniently and with far greater precision. The water passes in series through all of the internal dephlegmators, so that there is but one water control valve and one overflow requiring attention. The amount of water required by this system for refluxing is frequently as low as one-half that employed by the external reflux condenser, and we have actual tests on record indicating steam consumptions of 35 to 50 per cent of that required by the less efficient apparatus referred to. At the same time, due to the very sharp separations effected, it is possible to greatly reduce the percentage of higher and lower boiling impurities in the main concentrate, namely, crude toluol, thus materially lessening the difficulty and cost of the subsequent refining operations. Other impurities which, due to proximity of boiling points, are generally regarded as inseparable, may sometimes be eliminated by this type of still head.

Chemical Treating Process

Proceeding next to the subject of chemical treatment, it seems that this must remain, for the present at least, a rather clumsy makeshift, obtruding itself in the midst of an otherwise fairly well ordered process. For sheer

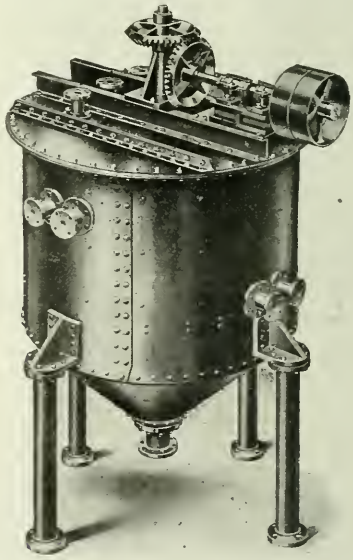

FIG. 9. CHEMICAL WASHER

lack of a worthy substitute, it becomes necessary to adhere to the established procedure involving the treatment of large batches of crude toluol with small doses of chemicals, imitating on a large scale the laborious separatory-funnel laboratory method of adding, shaking, settling, drawing off, and so on, repeatedly. Olefines and similar unsaturated compounds, because of proximity of boiling points or due possibly to the formation of constant boiling-point mixtures, have not been separated from toluol by distillation alone. Therefore sulphuric acid is employed to form water-soluble sulphonates which then may be removed by settling and separation of the acid layer, followed by neutralization with alkali together with thorough washings with

water. These operations are carried out in the so-called washer, illustrated in Fig. 9. The washers are lead-lined for the sulphuric acid treatment and of plain steel construction for the alkaline treatment. They are closed tight, with removable cover sections to minimize evaporation losses, and provided with high-speed screw agitators and cylinders to cause thorough mixing. The acid washer has lead cooling coils suspended just below the liquor level to remove the heat generated by the

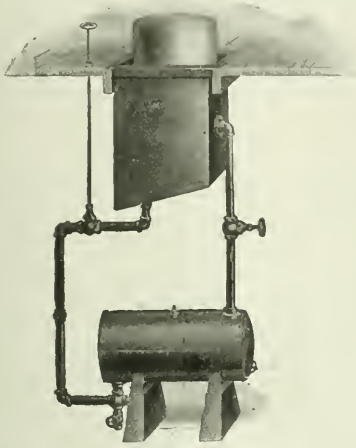

FIG. 10A. ONE-DRUM PATENT AUTOMATIC DISSOLVER

acid reaction. The balance of equipment for the chemical treatment consists of a lead-lined tank for acid storage and a plain steel tank for caustic soda solution.

The handling and dissolving of caustic soda is always a disagreeable and even dangerous operation. Actual first-hand experience with this troublesome material some years ago has since led us to devise dissolving and handling apparatus that seems worthy of mention in the present connection because it so effectually eliminates the usual difficulties. Fig. 10 illustrates two standard sizes of our dissolver as now extensively employed for dissolving whole cakes of caustic soda. Solution is effected rapidly and automatically by the positive circulation caused by the difference in gravity betweel the heavy solution and the much lighter cold water with which the outfit is at first charged. The whole caustic cakes are supported by a heavy cast iron grid in the upper part of the tank; the system is filled with water, so as to partially submerge the cakes, and solution then proceeds to completion without aid of heat or stirring. For very heavy solutions a thermo-syphon is placed in the circulation riser for heating the water to increase its solvency. This, however, is not necessary for producing 30 deg. B. and weaker solutions.

These dissolvers are made in sizes to handle one, two, four, five and ten whole cakes at a time. We also have devised a very convenient form of lifting tongs, capable of gripping the bare caustic cake as it lies horizontally on the floor and permitting the cake, upon lifting, to swing into a vertical position ready for lowering into the dissolver. Thus the entire operation may be carried out in safety without touching or breaking the original cake, with entire saving of steam or power for stirring, and without labor or attendance except as required to charge the dissolver at the start. We have come to consider this simple equipment as forming an essential part of any operation involving the use of considerable quantities of caustic alkali.

Refining Stills

The final rectifying or refining operation is of necessity a periodic or batch process. If a reasonably uniform crude toluol could be produced readily, this depending in turn upon uniformity of composition of the crude light oils, notwithstanding their widely different sources, then it would be feasible to employ a continuous refining still with all the advantages in respect to economy attending continuous operation. If a prediction may be based on parallel development in allied fields, it seems reasonable to look forward to continuous benzol and toluol refining as a highly desirable ultimate aim made possible by eventual standardization of preliminary methods of production with consequent control of light-oil composition. Until this more advanced status materializes, a conservative policy seems to require adherence to the batch refining process. The latter lends itself to a great variety of changing conditions without seriously affecting the ultimate product, toluol-pure. Mistakes made in previous operations can generally be remedied through the medium of a final periodic distillation. The continuous still, on the contrary, is rather inflexible, demanding, especially in the case of a refining operation, fixed conditions which cannot yet be counted upon.

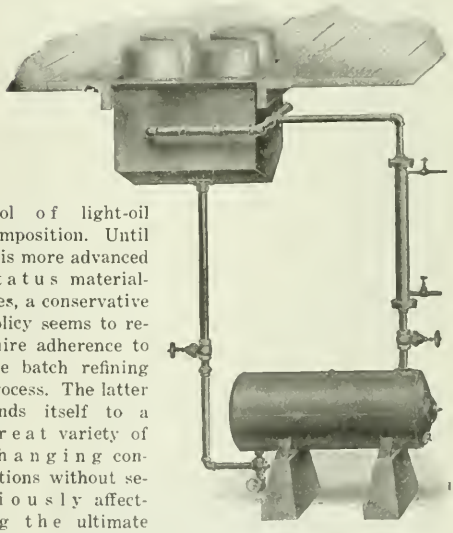

FIG. 10B. FOUR-DRUM PATENT AUTOMATIC DISSOLVER WITH THERMO SYPHON

The type of periodic or batch still usually employed in the toluol refining operation is illustrated in Fig. 11. This apparatus is distinguished by having the familiar external reflux condenser or dephlegmator. The column is of the well known boiling-cap or bell-and-seal type, constructed throughout of cast iron and steel. This standard type of still is furnished by all still manufacturers, our particular make claiming attention only in respect to improved results that may be due to our use of a novel form of slotted vaporizing cap which insures very thorough contact between ascending vapor

and descending liquor within the column, as well as to other minor details of construction which add to the life of the apparatus and the convenience attending its operation.

In this connection it is desired to call attention to an apparently wrong impression that appears to exist in respect to column construction as required for toluol refining. We have noted various detailed descriptions of columns for the purpose, none of which seems to grasp the significant underlying facts which determine the real merit of one type as compared to another. There are, for instance, specific allusions to mysterious column dimensions, such as 3 ft. 3 in. in diameter, with chambers 12 in. to 14 in. in height, conveying the incorrect idea that upon such minor points depend the satisfactory production of toluol. Another article explains that a column for one purpose is required to have serrated caps or bells, and for another purpose the serrations are omitted, but without giving reasons. These statements are mentioned not for their intrinsic importance, which may not be great, but merely as they represent the general tone of the published information in question. Details are always interesting and may be helpful when stated parenthetically for the purpose of illustrating broad discussion. Our criticism refers to the undue emphasis laid upon unessential details and non-representative apparatus types, leading to the inference that classic examples have been set forth, arrived at by a careful exclusion of all but the best. All this may be explained, possibly on the grounds of blind description of accidental apparatus that happened to come within the limited experience of the particular writer. The unfortunate result is that the misleading information, coming from supposedly authoritative sources, inclines the uninformed buyer of apparatus to insist on the absurd and non-essential specifications exactly as published, and the opportunity to educate him to a sane understanding of important determining factors is completely lost. Ignorance, which might have been partly dispelled, has been more firmly grounded by thus setting forth superficialities in the guise of real knowledge.

It must be made clearer to those concerned that column and still details are subject to considerable variation. We have employed column sections as low as 4 in. in height with good results. We regularly make them 6 in., 8 in. or 10 in. high, or higher, as required to obtain a proper balance between desired capacity and economical construction, uninfluenced generally by the particular material to be treated. Serrated caps are always better than plain dipping bells. The horizontally slotted cap, as originated by us, offers certain advantages in respect to release of bubbles at a uniform depth of liquid, more thorough vapor liquor contact and low column back pressure. We hardly could claim that some one's else column would not produce toluol because our patent caps were not used. It should be realized that these differences are mainly of degree, just as one type of gun may offer certain advantages over another, without excluding either type. Would it not, therefore, have been the part of wisdom to leave details of construction to reliable builders of the necessary apparatus, placing emphasis instead upon matters of broader meaning, so that the uninitiated might be helped to a reasonably comprehensive understanding of the tools available for performing the task confronting him. As matters now stand, it will be decided quite naturally that the slightest variation from narrow and rather obsolete specifications, already published, of necessity rejects available equipment which in reality may be far superior to the narrowly defined examples set forth. We are already encountering and endeavoring to combat the retarding effects of this ill-advised yet influential information. If some manufacturer had arranged a campaign solely to favor his particular type of apparatus, the incidental propaganda could not have been more skillfully planned and disseminated. In this case, undoubtedly with the most praiseworthy intentions, the same results are brought about and at a time when intelligent conceptions are badly needed and ill-founded prejudices become serious obstacles in the way of wisely directed co-operative action.

Periodic Toluol Refining Still

Returning to the subject of refining stills, Fig. 12 illustrates the Lummus periodic refining still with patented internal reflux system. We especially recommend this still for toluol refining, in view of its very high fractionating efficiency and economy of operation. It should be plainly understood, however, that the standard apparatus illustrated in Fig. 11 is very well adapted to toluol refining, the difference in

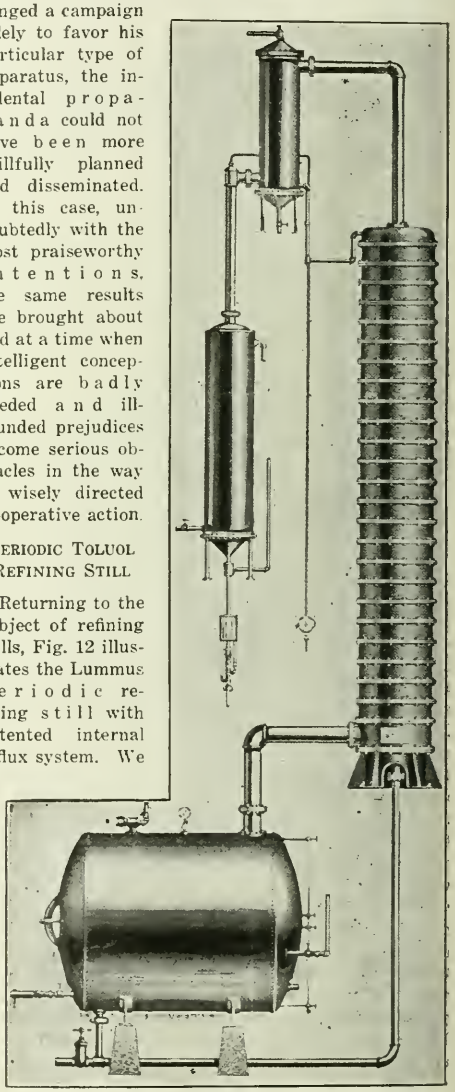

FIG. 11. BENZOL REFINING STILL WITH EXTERNAL REFLUX

favor of the more highly developed apparatus being one of degree only. That is to say, both stills are capable of turning out toluol-pure, but the Lummus type will do so with surprisingly greater economy in respect to steam and water, and the sharper separations permitted result in maximum yield of toluol-pure in one operation with correspondingly small yield of intermediate fractions requiring accumulation and subsequent re-distillation.

The Lummus refining still is constructed throughout of cast iron and steel. The still proper, or boiling kettle, is equipped with high-pressure steam coils arranged in separate groups or bundles to facilitate removal through the specially large manhole for repairs or replacement. The heating surface is arranged in most approved form, that is, a number of comparatively short tubes connected in parallel so as to maintain the velocity of the steam within the tubes and maximum average temperature difference throughout their entire length. There are no threaded joints inside the still. All joints are welded to avoid any possibility of internal steam leaks. The still is also provided with a perforated sparger pipe for injecting live steam, as in some instances preferred for distilling over the higher boiling components. The distilling column, because of its efficient design, may be considerably shorter than is necessary in the case of the standard still, and accordingly requires less building head-room. The chambers of the column are equipped with Lummus boiling caps and trapped return pipes, and the internal reflux system is in all respects similar to that described in connection with the continuous concentrator. All of the reflux tube bundles are removable without dismantling the column. The construction is very simple and durable, with all parts accessible for inspection, cleaning and repairs. The final condenser is of our vertical tubular accessible type arranged for easy cleaning of both inside and outside tube surfaces. This may be accomplished in position by removal of water jacket, vapor bonnet and liquor basin without disturbing connections and set-up of tube bundle. The outfit further includes the usual accessories, such as measuring product gage, recording thermometer, pressure and vacuum safety valves, gage glass, steam trap, etc. We have devoted considerable study during the past four years to the matter of suitable gaskets for benzol and toluol work. As a result, three types of gaskets are now successfully used for this sort of work, according to the nature of the joint to be made up.

Summarized Recommendations

Our recommendations in respect to toluol concentrating and refining are as follows:

Continuous concentration, applied to the preliminary distillation of crude toluol, insures maximum and uniform output. The continuous still once adjusted may be held at top speed production day and night except for occasional interruptions that are likely to occur in the case of all mechanical devices.

The commonly employed batch concentrating process wastes many hours of the day in dumping, charging, heating and cooling. This loss of time is entirely avoided by continuous operation.

The three products—crude benzol, crude toluol and solvent naphtha—are produced simultaneously, instead of one at a time as in the case of periodic operation. The consequent saving of time and increased output are obvious.

The Lummus double column continuous concentrator, including the internal reflux system, insures maximum economy in respect to steam and water consumption and the highest possible concentration of toluol in the crude toluol fraction. Troublesome impurities are eliminated at the start, with consequent saving of time and materials in subsequent operations.

By the interchange of heat between the crude toluol feed-liquor and the hot solvent naphtha discharged from the concentrating process, a material saving of heat is effected, all of which is entirely lost in the present periodic concentrating process. This is an especially important saving as applied to the large volume of crude light oil that must be handled to produce a comparatively small volume of crude toluol, the subsequent periodic refining of which does not involve heat losses of too great consequence.

The chemical washing apparatus, although in accordance with established practice, is of simple, durable construction, careful attention being given to mechanical features and means for preventing undue evaporation losses.

The caustic soda nuisance is eliminated through the use of dissolvers, which operate automatically, without steam or stirring, handling whole cakes rapidly and with minimum attendance.

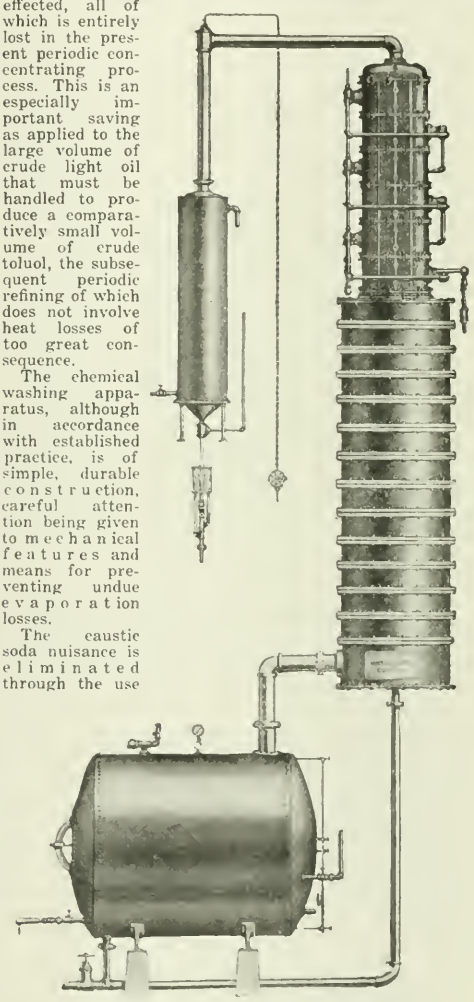

FIG. 12. TOLUOL REFINING STILL WITH PATENT INTERNAL REFLUX SYSTEM

The Lummus periodic refining still, with internal reflux system, operates with high economy of steam and water, effecting sharp separations of objectionable impurities and insuring maximum yield of toluol-pure in one operation.

Needed Improvement of the Chemical Treating Process

We are impressed with the many shortcomings of the thus far unavoidable intermediate refining operation, involving treatment of the crude toluol fraction

with chemicals for the removal of certain impurities that have appeared to be inseparable by distillation alone. Certain remarks in this connection, although perhaps more or less inconclusive, may offer something in the way of a suggestion toward future improvements in this direction. The numerous difficulties inherent in the present method of chemical treatment appear to be sufficiently obvious. At the best, it is an inconvenient and expensive step, worthy of serious effort directed toward its entire elimination or at least drastic improvement. In the first place, usable olefines and valuable phenols, if present, are entirely lost through this process. The consumption of sulphuric acid and caustic soda cannot be disregarded, and the many troublesome features introduced by the necessity of handling these materials, including the regeneration of the acid, add quite a burden to what would otherwise be a fairly clear-cut procedure. The greatest disadvantage of the chemical treatment, however, seems to rest in the unavoidable shrinkage in respect to toluol, not entirely accounted for by the mere removal of impurities other than toluol. This may be explained on the basis of sulphonation and evaporation losses, but the fact remains that valuable toluol disappears, a loss which, under present circumstances, assumes a particularly serious aspect. Furthermore, the process as now carried out, involving the periodic handling of large batches of material, certainly is not conducive to economy; and the skill and judgment demanded on the part of the operator introduces the human element and dependence thereon, which is always an obstacle in the way of efficient production.

We have been devoting considerable thought and work to this problem and feel free to state that progress thus far has been very encouraging. In view of radical departures from usual procedure, we would not consider it advisable to publish at this time the as yet incomplete results of our investigation, and must at the same time acknowledge that our experiments to date are not sufficiently final in their indications to warrant any positive prediction of success. At present we merely wish to call attention to the need of improvements in this quarter, with the hope that later we may be in position to contribute information that may prove helpful in the way of suggesting a practical solution of this problem. Should the completion of our work meet with success, we will report our findings to the proper authorities and then publish, or otherwise make available, such information as may appear generally useful.

Central Concentrating and Refining Stations

In closing this second part of our report, it is desired to comment briefly on the matter of centralized toluol concentrating and refining plants. Assuming the use of tar as the absorbing medium in the absorbing and stripping process, there appear to be no serious obstacles in the way of shipping the recovered crude light-oil fraction to large central stations for concentrating and refining, as required to produce toluol-pure. The fact that the tar makes but one passage through the system means that loss of absorbent, present in the crude light oil, may be disregarded. It stands to reason that the recovery of the light oil is a sufficient strain on the resources of the gas manufacturers, especially if smaller producers are later to be requisitioned; and it would seem undesirable to attempt the more complicated work of concentrating and refining at the various sources of toluol production, because of the large number of small refining units that would be required, which, even under the most favorable circumstances, could not turn out economically the uniform product demanded. On the other hand, a comparatively few very large refining plants, properly distributed throughout the country, could be designed and built to operate with very high economy, in that the very satisfactory results, in no other way attainable, would represent the least expense both in respect to equipment and operating cost. This plan would render possible the use of highly organized apparatus installed in very large units, which, together with scientific control and intelligent supervision, otherwise out of the question, would insure a dependable and uniform toluol production in a high degree favorable to wholesale munitions manufacture. Under any other arrangement, inadequate and inefficient types of apparatus invariably would be resorted to, and the extensive supervision necessary to maintain essential standards seems wholly impracticable. The consequent loss would, in our opinion, amount to appalling figures, due not only to the increased cost of refining, but to actual waste of toluol, measured perhaps in millions of gallons.

We therefore conclude this report with the plea that this matter of centralized refining be given most careful consideration. In fact, the arguments in its favor are so obviously convincing that we are inclined to assume that work, which we understand is already in progress, anticipates refining at large, carefully planned central refineries. These may require extra time to design and build, but in our opinion it would be better to provide extensive storage for crude light oil, produced during the interval, rather than to make the mistake of installing small refining plants for operation by the individual light-oil producer.

Part three, concluding our recommendations in respect to intensive toluol production, will deal specifically with absorbing and stripping plants graded to meet the requirements of various classes of light-oil producers, together with large central refining stations of capacity to handle the light-oil output from their respective districts. It is our hope to include brief schedules of requisite equipment for various plant capacities together with a general idea as to comparative costs.

(To be continued)

Navy Still Needs Binoculars, Spy-Glasses and Telescopes.—The Navy Department has issued a statement announcing that the Navy is still in need of binoculars, spy-glasses and telescopes. The use of the submarine has so changed naval warfare that a greatly increased lookout system is needed. All articles should be tagged, giving the name and address of the donor and forwarded by mail or express to Hon. Franklin D. Roosevelt, Assistant Secretary of the Navy, care of Naval Observatory, Washington, D. C. Articles not suitable will be returned and those accepted will be keyed and returned, as far as possible, at the close of the war. The Government will pay one dollar as rental for each article in order to comply with the law. An attempt will be made to furnish a little historical summary with those instruments which are used and are returned after the war.

Sulphur Dioxide Method for Determining Copper Minerals in Partly Oxidized Ores*

By CHARLES E. VAN BARNEVELD and EDMUND S. LEAVER

MILLING practice at the porphyry copper mines of the Southwest is in a transition stage because of the rapid changes following the introduction of flotation. Among the several problems that are receiving earnest attention from the operating companies is the recovery of the copper minerals forming the complex ores of the oxidation zone of the deposits.

This problem is under investigation at the Tucson experiment station of the Federal Bureau of Mines. A survey of the status of present laboratory practice brought out the need of a correct and rapid method for the selective determination of the quantity of copper in the sulphide form, on the one hand, and of that in the form of combined oxides, carbonates, silicates, and native or metallic copper, on the other hand, in partly oxidized ores and in mill products from these ores. Such a method is necessary for control determinations on flotation mills treating sulphide ores and also on lixiviation works using either acids or alkalines as the active solvent for the copper in oxidized and silicate form. For convenience in this report such copper is termed "oxidized copper."

Sources of Error in Methods in Use

The methods in common use for selective determination of copper minerals are the sulphuric acid method and the ammonia method. Both are unsatisfactory.

SULPHURIC ACID METHOD

The sulphuric acid method, in which a 5 per cent solution of cold sulphuric acid is used to dissolve all the oxidized copper, is unreliable for several reasons. A certain amount of metallic iron (ranging from one-tenth to one-half of one per cent) is nearly always present in the sample, introduced by the various crushing (mill) and pulverizing (laboratory) processes. This metallic iron precipitates more or less metallic copper from the copper sulphate solution formed by leaching with dilute sulphuric acid, thus giving correspondingly low oxidized copper returns. Another source of error in the same direction is the fact that dilute sulphuric acid dissolves only one-half the copper present as cuprite (Cu_2O). A serious source of error in the opposite direction, making for high oxidized returns, is the fact that chalcopyrite, bornite, and chalcocite are more or less soluble in dilute sulphuric acid (see Table I). Hence, more or less copper in sulphide form is reported as oxidized copper. It sometimes happens that the plus error due to solution of some of the copper in sulphide form is largely compensated by the minus error due to partial solution of cuprite and to deposition of copper on metallic iron. The majority of the ores tested by the writers show high oxidized and low sulphide returns, and check samples show considerable variation.

*Contribution from the Tucson Station, U. S. Bureau of Mines. Printed by permission of the Director.

The results of tests with chalcocite and chalcopyrite, showing the solubility of the copper content in different reagents, are presented in Table I.

TABLE I—RESULTS OF LEACHING CHALCOCITE AND CHALCOPYRITE WITH 5 PER CENT SOLUTIONS OF DIFFERENT REAGENTS

The mixtures were agitated two hours on a bottle-rolling machine. Five grams of pure mineral was used for each of the mesh sizes indicated

200 to	2.07	22.70	Do.	0.56	0.93	Do.

AMMONIA METHOD

The ammonia method, in which a 5 per cent solution of either ammonia or of ammonia and ammonium carbonate is used to dissolve the oxidized copper, is even more unreliable than the sulphuric acid method. The results in Table I show that both chalcopyrite and chalcocite when pulverized are decidedly soluble in solutions of ammonia and ammonium carbonate, the finer the material is ground the greater is the degree of solubility. On the other hand, complete solution of the oxidized copper is rarely attained. This defect is most noticeable in ores having a siliceous gangue and in ores carrying chrysocolla. The solvent gelatinizes the silica and it appears that the formation of this gelatinous, spongy mass prevents complete decomposition of some of the copper mineral, in addition to holding dissolved copper during filtration.

Sodium Tartrate Method

While the investigation at the Tucson station was in progress, an improved method was developed by H. D. Hunt and R. V. Thurston, of the research laboratory of the Miami Copper Co. This method was brought to the writers' attention after the completion of their own work on the sulphur dioxide method described in this paper. A description of Hunt and Thurston's, which may be called the sodium-tartrate method, has been published in the September, 1917, issue of the Colorado School of Mines Magazine.[1] The procedure is essentially as follows:

PROCEDURE

Place 2 grams of pulp in a beaker, add 20 cc. of a

[1] Hunt, H. D., and Thurston, R. V. The determination of oxidized copper in ores. Colorado School of Mines Mag., Vol. 7, September, 1917, pp. 157-158.

solution of caustic soda-sodium tartrate, and boil the mixture gently 5 to 10 minutes with occasional shaking of the beaker. To the hot mixture add 25 cc. of a 20 per cent solution of ammonium sulphate; heat for 10 minutes. Filter; wash several times with a hot solution of ammonium hydroxide and ammonium sulphate, and finish the washing with hot water. Neutralize the filtrate with sulphuric acid and add 2½ cc. of concentrated nitric acid. It is now ready for electrolysis.

The first treatment with solution of caustic soda and sodium tartrate effects complete and rapid solution of the azurite, malachite, and melaconite, and partial solution of the cuprite. The rest of the cuprite is dissolved later. The chrysocolla also goes into solution. Care must be taken not to boil to dryness or to a small volume. The reagent must be of sufficient strength to redissolve the copper hydroxide first formed by the action of the solution on the oxidized copper minerals in the sample. The ammonium sulphate solution has a two-fold function. It converts the excess sodium hydrate into sodium sulphate and it forms ammonium hydroxide which dissolves any remaining cuprite.

SOLUTIONS REQUIRED

The following stock solutions are required: Sodium hydrate-sodium tartrate solution, consisting of 100 grams of sodium hydrate and 50 grams of sodium tartrate dissolved in 1000 cc. of distilled water; ammonium sulphate solution, consisting of 250 grams of ammonium sulphate in 1000 cc. of distilled water; and ammonia-ammonium sulphate solution for washing, prepared by adding 100 cc. of ammonium hydroxide and 100 grams of ammonium sulphate to 1000 cc. of distilled water.

POSSIBLE SOURCES OF ERROR

In testing out this method, the writers found that it gives fairly satisfactory results on the low-grade porphyry ores for which it was developed. The method is, however, subject to two well-defined inaccuracies.

One of these arises from the fact that chalcocite is decidedly soluble in ammonia. Washing with hot solution of ammonia and ammonium sulphate unquestionably dissolves more or less copper in the form of chalcocite from the mass on the filter paper. Several tests were made of 2-gram samples containing 3 to 4 per cent of oxidized material and varying proportions of chalcocite. Mixtures containing 8, 16, and 24 per cent copper as chalcocite showed respectively 0.18, 0.33 and 0.45 per cent dissolved in washing and erroneously reported as excess oxidized copper.

Another source of inaccuracy as regards ores containing chrysocolla, results from the difficulty of washing all the dissolved copper from the gelatinized spongy mass on the filter paper. Mixtures containing 2½ to 3 per cent copper as chrysocolla showed losses ranging from 0.05 to 0.1 per cent; and mixtures containing 5 and 7½ per cent in this form, respectively, showed losses of 0.33 and 1.42 per cent. These errors tend to balance each other for ores containing both chalcocite and chrysocolla in small amounts. In analyses of ores containing less than 5 per cent copper, the resultant error (see Table II) is not serious.

Sulphur Dioxide Method

The experiments with the sulphur dioxide method were made with the following requirements in mind:

1. The method must be applicable to a wide range of ores, and must be thoroughly reliable and rapid.
2. Copper sulphides, especially the more easily decomposed chalcocite, must not be affected by the reagent used.
3. Metallic iron must not affect the determination.

The method evolved is based on a large number of experiments, the results of which show conclusively that cuprite, melaconite, malachite, azurite, chrysocolla, and metallic copper, when finely pulverized, are readily and completely soluble in sulphur dioxide solution (sulphurous acid). Copper sulphides are not attacked, no matter how finely pulverized the mineral may be nor how long the time of contact. The two essential features of the method are: (1) fine pulverization in order to completely free the particles of copper minerals from the gangue; (2) the powdered mineral must be kept in suspension by shaking or rolling during the lixiviation or solution period.

PROCEDURE

The procedure in the sulphur dioxide method is as follows: Place 2 grams of pulp ground to a fineness of 100 to 150 mesh in a bottle, add 100 cc. of a 3 per cent solution of sulphur dioxide. Seal the bottle and agitate by rolling ½ to 2 hours. Filter; wash the residue with sulphur dioxide solution; add the washings to the filtrate, which will contain in solution all oxides, carbonates, and silicates of copper and all metallic copper. Add 5 to 10 cc. of nitric acid. Boil down to 20 cc. Dilute with distilled water to 150 cc. and determine the copper by the electrolytic method in the usual way.

The residue from filtration contains the unaltered and undissolved copper sulphide. In the experimental work the copper present as sulphide was separately determined in order to check the determination of oxidized copper. Ordinarily this step would not be necessary. In analyses of the low-grade porphyry copper ores of the Southwest, the sulphides may be readily decomposed and all the copper dissolved by proceeding as follows: To the residue add 5 cc. of sulphuric acid and 10 cc. of nitric acid and boil until dense white fumes appear. Add 5 cc. of nitric acid and dilute with distilled water to 150 cc. Determine the copper by the electrolytic method. This method of determining copper in the residue is not suited for heavy sulphide ores containing interfering bases, and for such ores standard methods should be used.

PREPARATION OF SOLUTION

Although sulphur dioxide solution (sulphurous acid) may be readily purchased, it is decidedly unstable; hence the solution should be prepared in the laboratory as needed. Small quantities are easily made by adding moderately strong sulphuric acid to scrap copper tinned on one side; the resulting sulphur dioxide gas is absorbed in water. For continuous work it is better to purchase liquid sulphur dioxide in steel cylinders and drums, which are obtainable in sizes ranging from 6-pound to 200-pound capacity. In the first experiments at the Tucson station the sulphur dioxide gas was introduced directly into the bottle containing the water and pulp. Much loss of gas resulted and the procedure was otherwise unsatisfactory.

Later the simple apparatus shown in Fig. 1 was evolved. The absorption tower *a*, 43 inches long, made

of ¾-inch to 1-inch glass tubing and filled with broken hard-burned fireclay, is set at an angle of 75 deg. between two glass bottles, *b* and *d*, of 3 to 5 gallons capacity, the bottle *b* being placed about 5 feet above the other bottle. The tower is open at the top and sealed at the bottom with a plug of sealing wax, *e*, through which two small glass tubes extend. The upper bottle, *b*, contains distilled water which is siphoned into the upper end of the absorption tower, the flow being regulated by a stop cock, *f*. A cylinder *c* (capacity 6 to 50 pounds) containing liquid sulphur dioxide is connected to one of the glass tubes extending into the absorption tower. On opening the valve of this cylinder the liquid sulphur dioxide issuing from the valve is gasified by the reduction in pressure and passes into the tower, where it is absorbed by the water from bottle *b*, converted into SO_2 solution of the desired strength and caught in the stock bottle *d*.

This apparatus gives entire satisfaction. With little attention a 3 per cent solution of sulphur dioxide may be produced at the rate of 3 liters per hour. The cylinder containing liquid sulphur dioxide, indicated in the sketch, may be replaced with a gas generator.

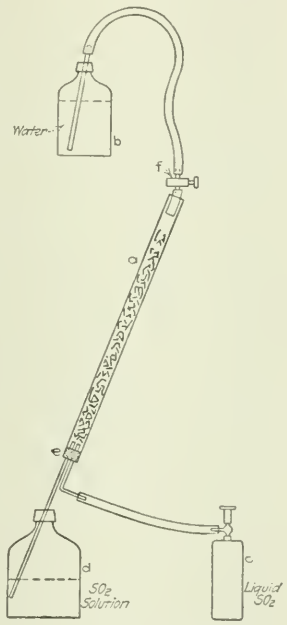

FIG. 1. APPARATUS FOR PREPARING SO_2 SOLUTION

STRENGTH OF SOLUTION AND TIME OF CONTACT

Considerable variation as regards strength of solution and time of contact will be necessary in treating different ores from different localities. In general, a solution containing 3 per cent SO_2 should be used. With some ores much weaker solutions, as low as 0.75 per cent SO_2, will do the work. Merely introducing the pulp into the solution, shaking the bottle for a few minutes, and letting it stand, will not dissolve the copper; constant agitation is essential. For a small number of tests a bottle-agitating machine will give satisfactory results. For analytical work where large numbers of samples are run, as in a mine laboratory, a bottle rolling machine will be found more satisfactory, not only for this purpose but for all solutions requiring constant agitation. The time of contact necessary to completely dissolve the oxidized copper minerals was found to vary from ½ to 2 hours. Most of the ores and products tested gave complete recovery in half an hour and the most refractory ores yielded in less than two hours.

To determine the strength of the sulphur dioxide solution, the following adaptation of a well known reaction is recommended; it is based on the fact that introducing either weak or concentrated sulphurous acid into a solution of iodine will result in the complete oxidation of the sulphur dioxide.

Prepare an iodine solution by dissolving 16.8 grams of potassium iodine in distilled water, adding 8.4 grams pure resublimed iodine, and shaking until the iodine is completely dissolved. The more concentrated the potassium iodide solution, the more readily will the iodine dissolve. Bring the solution to proper strength by adding enough distilled water to make a volume of 1 liter, and standardize by the thiosulphate method.

The determination is made as follows: To a measured quantity of standard iodine solution add slowly with constant stirring the proper volume of sulphur dioxide solution. So regulate the volume of iodine solution used that the mixture always contains a decided excess of iodine over the quantity required to oxidize the sulphur dioxide being added. An excess of sulphur dioxide causes the solution to clear and to lose its dark red color. If an excess of sulphur dioxide is added the determination is spoiled, and the test should be repeated with fresh sulphur dioxide solution and larger quantity of iodine solution. Thus, there is a direct ratio between the strength and quantity of sulphur dioxide solution and the quantity of standard iodine solution. In general, for solutions containing 1 to 3 per cent sulphur dioxide 1 cc., and for weaker solutions 20 cc., of standard iodine solution should be used. The mixture is then titrated by the thiosulphate method to determine the quantity of iodine remaining in the mixture. The difference between this quantity and the total quantity of iodine represents the iodine used in oxidizing the sulphur dioxide. The strength of the sulphur dioxide solution may then be calculated according to the formula:

$$SO_2 + H_2O + 2I = 2HI + SO_4$$

COMPARISON WITH OTHER METHODS

Comparative results obtained with the four methods described on ores and mill products from the Morenci,

TABLE II—RESULTS WITH THE FOUR METHODS COMPARED

Source of Sample	Copper Content Per Cent	Oxidized Copper (Oxide, Carbonate and Silicate): By Sulphur Dioxide Method, Per Cent	By Sodium Tartrate Method, Per Cent	By Sulphuric Acid Method, Per Cent	By Ammonia Method, Per Cent
Inspiration mill feed	1.31	0.35	0 33	0.41	0.36
Inspiration mill slimes	0 43	32	28	.35	.07
Miami complex ore	2 24	1 05	1 02	1.32	.91

Utah copper mill feed	89	60	56	63	37
Utah copper mill tailing	63	07	06	11	09
Miami ore, special test:					
20 mesh	2 25	1 06	0 96	1 18	0 83 to 0 90
48 mesh	2 25	1 05	0.98	1 28	0 62 to 0 98
65 mesh	2 25	1 08	1 00	1 30	0 95 to 1 10
100 mesh	2 25	1 06	0.97	1 32	0 91 to 1 10
150 mesh	2 25	1 07	0.92	1 32	0 92 to 1 06
200 mesh	2 25	1 06	1 02	1 34	0 88 to 1 09

Note.—In the sulphur dioxide method any metallic copper present would be reported as oxidized copper. In the other three methods, metallic copper would be reported as sulphide.

Globe, Ray, and Ajo districts in Arizona, from Chino, from Bingham, Utah, and from Ely, Nev., are presented in Table II. The table shows that, compared with the sulphur dioxide method, the results for oxidized copper are high with the sulphuric acid method and low with the ammonia method. The sodium tartrate method shows uniformly and slightly lower returns. The last sample in the table, designated "Miami ore, special test," was crushed to 20-mesh size, special care being taken to prevent overcrushing. Five portions were then taken and crushed with the same care to the successive sizes listed. The uniform results for oxidized copper by the sulphur dioxide method is evident. The results with the sodium tartrate method, which was developed on this class of ore, show more variation and are slightly lower. The sulphuric acid method shows high returns, which are progressively higher for the finer sizes. Results with the ammonia method are low and show considerable variation.

Conclusions

Sufficient work has been done with the sulphur dioxide method to substantiate the following claims:

1. Cuprite, melaconite, malachite, azurite, chrysocolla, and metallic copper are dissolved rapidly and completely.
2. Chalcocite and chalcopyrite are not affected.
3. Metallic iron in ordinary quantities, even up to 3 per cent, dissolves rapidly and has no effect on the determination, provided there is a strong excess of SO_2.
4. There is no gelatinization of silica, and the possible loss of copper from this cause, noted in analyses by the other methods described, is eliminated.
5. The method is applicable alike to high-grade and low-grade ores. The manipulation is simple and the possible sources of error are few. One chemist can keep a 6-unit electrolytic outfit working to full capacity on porphyry ores.
6. Any metallic copper present would be reported with the oxidized copper. If a separate determination of metallic copper is considered necessary this may be made by amalgamation, preferably in an amalgamated copper pan.
7. Crushing fine enough to liberate completely the mineral particles is essential. Ores containing an appreciable proportion of chrysocolla should always be pulverized to 150 mesh.

Manganin.—Mr. M. E. Leeds of Leeds & Northrup, Philadelphia, states that manganin is difficult to obtain and is not to be had in any desirable quantities. At least one of the substitutes offered for it by an American manufacturer is, however, fully as good as manganin. It is, however, equally difficult to get, and, to the best of his knowledge, is not being produced in any sufficient quantity. There are probably several American manufacturers of alloys who could produce as good manganin as that made in Germany, and it is not so much research that is needed to help us out of the situation as it is greater productive capacity for special alloys. The manufacturers who are competent to make manganin are so overworked with orders which the Priority Board would probably consider more important that it is very difficult to get them to take the matter up.

Synopsis of Recent Metallurgical and Chemical Literature

Manganiferous Iron Ores.—U. S. Geological Survey Bulletin 666-EE by E. C. Harder gives valuable data on the deposits of manganiferous ores in the United States and their possible utilization. The dependence of the United States on imported high-grade manganese ore and ferromanganese is well known to steel makers and other users of manganese. Normally the high-grade manganese ore produced in this country constitutes less than 2 per cent of the total amount of manganese ore consumed, not including the ore represented by the manganese imported in the form of the alloys ferromanganese and spiegeleisen. During 1916 the domestic production was about three times that of 1915, largely on account of the high prices paid for ore. The exploration for new deposits has also been stimulated, and many discoveries of manganese ore are being reported. Even with this outlook for increased production, however, the author thinks it not unduly pessimistic to say that the deposits of high-grade manganese ore in the United States will probably never be able to supply the manganese consumed in domestic industries. If, therefore, the importation of high-grade manganese ore were discontinued, numerous industries would be vitally affected. Of these the steel industry consumes by far the largest quantity of manganese. The author, after giving a description of the deposits in the United States and the production of the various states, summarizes his report as follows:

There are in the United States large quantities of manganiferous ores containing varying amounts of manganese. A very small proportion of these can be used in the production of high-grade iron-manganese alloys, but a large proportion can be used for lower-grade alloys, and nearly all can be used in making high-manganese pig iron. Compared with the manganiferous ores, the reserves of high-grade manganese ores in this country are insignificant. Hence, although a search for manganese ore is desirable, a more promising solution of the manganese problem would seem to lie in the direction of the utilization of low-grade manganiferous ores. Up to the present time the use of these ores has been very slight. Until a few years ago they were considered to have little value and were mined only incidentally. In the West manganiferous ores would not be mined were it not for their association with ores of other metals.

There are several ways in which the utilization of manganiferous ores may be brought about: (1) It has been suggested that by methods of concentration resulting in the elimination of iron, silica, or other constituents a product high in manganese might be derived from them. Such concentration has been attempted locally but with very little success, owing mainly to the intimate mixture which manganese generally forms with associated materials. (2) The steelmaking practice might be changed so that more spiegeleisen and less ferromanganese would be used for deoxidizing. By the addition of small quantities of high-grade manganese ore much of the manganif-

erous iron ore could be used in the manufacture of spiegeleisen. (3) The most effective solution, however, as has previously been suggested, seems to be to so change the practice in the manufacture of basic open-hearth steel as to make possible the use of high-manganese pig iron. Experimentation along this line is extremely desirable. The successful application of such a change would make large reserves of manganiferous iron ore commercially available and would greatly decrease the quantity of high-grade manganese ore consumed.

Ball Mill Tests at Inspiration.—Mr. C. T. VAN WINKLE, in a paper to be presented at the New York Meeting of the American Inst. of Mining Eng., February, 1918, on "Recent Tests of Ball-Mill Crushing," gives some hitherto unpublished data on the test conducted at the Inspiration mill at Miami, Ariz., early in 1916, when two sections were added to the mill. After outlining the experience of the Miami Copper Co. (Franke, Trans. A. I. M. E., Vol 47, page 50) and early work by Dr. Gahl at Inspiration (Trans. A. I. M. E., Vol. 55, page 576, and *Metallurgical & Chemical Engineering*, Vol. 15, page 393), the author continues:

"Early in 1916 the Inspiration company decided to add two sections to its mill, and an offer by Mr. Hardinge to equip a section with two of his mills without cost to the company was accepted. These mills were expected to do the work of the same number of Marcy mills, with much less power.

This test was begun April 4, 1917. A section comprising two 8-ft. Marcy mills equipped with 225-hp. motors, which had been in continuous operation since January, 1917, was used in comparison with a section comprising two 8-ft. Hardinge mills equipped with 150-hp. motors. Each of the Marcy mills took the original feed from the bin and, in closed circuit with a 6-ft. Dorr classifier, made a finished product.

The Hardinge mills were first arranged in tandem, the first mill taking all of the coarse feed, its product going to a Dorr classifier, the sands from which passed to the second Hardinge mill working in closed circuit with the second Dorr classifier. Each of the sections was equipped with an automatic scale so that the total or the hourly tonnage could be recorded and noted. The crushed product, the overflow from the Dorr classifiers, was carefully sampled in each case by automatic samplers. The daily report sheets of the finished product showed some variation from the desired 2 per cent on 48-mesh with both types of mills, but by applying a correction factor the final results, as tabulated, could be reduced to the basis of 2 per cent on 48-mesh. This correction factor was derived by Dr. Gahl from actual operating experience. The screen analysis of the feed was published in the *Engineering and Mining Journal*, September. 1916. The results are as tabulated below:

The daily reports show that various ball charges and various sizes of balls were used in the Hardinge mills; that the speed of the Hardinge was changed a number of times; various types of scoop feeders were used; the delays due to overloading the Hardinge mill, changing balls, etc., as mentioned, were very great. The Marcy mill continued with its ball load unchanged and practically without delays.

The record shows that the capacity of the Marcy mill was 130.5 per cent greater than the Hardinge, and the Marcy saving in power over the Hardinge was 34.04 per cent. At times the motors of both types of mills were slightly overloaded. As the power was measured by integrating wattmeters, this does not affect the results and comparisons given. The figures showing daily tonnage and kilowatt-hours per ton are averaged from the daily report sheets issued by the Inspiration management. These figures were accepted by the manufacturers of both mills, and there is no doubt as to their correctness.

Marcy Section		Hardinge Section	
Duplicate mills, 8 ft. by 72 in.		Duplicate mills, 8 ft. by 36 in.	
Spiral scoop feeders		Spiral scoop feeders on both primary and secondary mill	
Lining, Mn steel, Krupp type		Lining, Cr steel

	Marcy	Hardinge
Daily tonnage (dry), corrected to 2 per cent. on 48-mesh	1118	485
Kw.-hr. per ton crushed	8.52	11.42

No ball consumption was published by the Inspiration company on the Hardinge mills because many changes had been made in the ball load. The operation of the Marcy mills was in charge of the regular mill crew, while that of the Hardinge section was under the supervision of Mr. Hardinge and his assistants, who were at the plant from April 4 to June 11, when the test was discontinued. The ball consumption of the Marcy mill in the entire plant is 1.7 lb. of steel for each ton of ore crushed.

Determination of Temperatures by Eutectic Alloys.—In the Journal of the American Chemical Society for January, 1918, Dr. C. P. STEINMETZ of the General Electric Co. gives the results of some observations on the use of eutectic alloys in temperature determinations. He says the foremost advantage expected was the far greater independence of their melting point from the purity of the material. Any impurity, such as an excess of one or more constituents, should, in cooling, crystallize out when the freezing point is approached and the alloy thus thickens before solidifying, but the final freezing point remains that of the eutectic alloy. From experiments made on various alloys with melting points below 200 deg. C., it was found, however, that material impurities caused by metals which are not a constituent of the alloy may be harmful and are to be guarded against, but a considerable deviation of the proportions of the normal constituents of the alloy appears harmless. Even the harmful effect of a foreign metal impurity probably is limited to the cases where the addition of such metal forms a eutectic alloy of lower melting point. The following twelve alloys were found by the author in the range below 200 deg. which are eutectics or sufficiently near to eutectics in their composition to permit their use, and their melting points determined by observing the freezing curves, while stirring with the thermometer. A number of observations were made with each alloy, with slightly changed composition, and by interpolation the composition of the true eutectic estimated and checked by its freezing curve.

However, neither time nor facilities were available to go very far in the investigation, and the values given in the following table thus are only approximately those of the eutectic. It would be of interest to determine the exact composition of the eutectic. This could most conveniently be done by studying the shape of the cooling curve. In the eutectic, the curve of decreasing temperature of the melted alloy follows an approximate exponential down to the constant freezing temperature. If, however, the composition is not exactly eutectic, the cooling curve deviates from the exponential when approaching the freezing point, and the temperature decreases more slowly, while the non-eutectic part freezes out.

Low Melting Eutectic Alloys
(Approximate)

Melting point	Composition						Remarks	Temp. of undercooling
	Bi.	Cd.	Pb.	Sn.	Tl.	Zn.

[1]Wood's metal, expands after cooling.
[2]Rose metal, expands after cooling.
[3]Combustible above melting point.
[4]Cadmium solder. Lowest melting alloy not containing the expensive bismuth.
[5]Tin solder.

It is interesting to note that the alloys which do not contain bismuth are ductile, while the alloys containing bismuth are brittle, unless they contain a large percentage of lead and little if any tin or cadmium.

Effect of Hydrochloric Acid on the Nitrogen-Hydrogen Equilibrium.—At a recent meeting of the Faraday Society in London, Dr. E. B. Ludlam presented the results of an experimental attempt to simplify the difficult conditions of high temperature at high pressure under which the Haber synthesis of nitrogen and hydrogen to form ammonia takes place. Deville long ago proved that ammonia in the presence of hydrochloric acid gas was more stable than when alone, and it was therefore thought that the presence of hydrochloric acid during the synthesis would displace the equilibrium in the direction of the formation of ammonia by preventing the reverse change, and would remove the ammonia so quickly that the synthesis might be possible at atmospheric pressure. Some preliminary experiments gave negative results, and further showed that the problem of finding a catalyst suitable for use in the presence of hydrochloric acid was likely to prove a great difficulty. In later experiments the equilibrium was studied by attempting the reverse operation, that is, starting from ammonium chloride and decomposing it into nitrogen, hydrogen and hydrochloric acid. Various catalysts were used, but only iron gave positive results. The presence of ferrous chloride, however, introduced a new factor, and its volatility at a low temperature was a serious drawback. In any case the final equilibrium at 800 deg. C. was not displaced to any very considerable extent, and the direction of the formation of ammonia by the presence of hydrochloric acid. The result of the experiments, as far as they went, were therefore negative.

Recent Metallurgical and Chemical Patents

Catalyzers.—Four patents have been issued to Carleton Ellis, of Montclair, N. J., on catalyzers. The first relates to a finely divided catalyzer made by heating organic compounds such as oleates of catalytic metals, in the oil to be catalyzed. These organic compounds may be decomposed, setting free the catalyst (that is the metal) not as a pulverulent catalyzer, but as an oil colloid, the metal existing therein in a state of almost infinite subdivision, perhaps approaching molecular condition, and colloidally carried in a state of quasi solution, conducive to accelerated hydrogen absorption by the fatty or other organic materials. The second patent relates to nickel carbonyl. The third patent relates to a process of making a catalyst comprising the reduction of an organic nickel salt such as nickel acetate with a reducing gas. The fourth patent relates to a process of heating, while sealed from contact with air, a mixture of an organic compound of nickel or a metal having an atomic weight between 51 and 63.6, and a nitrate of the metal. A reduction takes place and metallic nickel or other metal used is produced. (1,251,201-2-3-4, Dec. 25, 1917.)

Metallic Alloys.—F. M. Becket of Niagara Falls, N. Y., has patented two alloy compositions (assignor to Electro Metallurgical Co.). The first calls for an alloy essentially of

Chromium	.....25 - 30	per cent
Carbon	..... 1.5 - 3	per cent
Silicon	..... 0.0 - 3	per cent
Iron	.....73 - 63.5	per cent

forming metal of extreme toughness, hardness and freedom from oxidation and rusting. The resistance to rusting increases with the silicon, although higher silicon induces brittleness. One of the alloys resisted an oxidizing atmosphere at 1100 deg. cent. continuously for two weeks without appreciable oxidation. The alloys are markedly fibrous, can be forged, annealed, tempered and machined, and are useful as an abrasive, as non-slipping surfaces, for turbine blades, cutting tools, and high temperature work. (1,245,552, Nov. 6, 1917.)

The second alloy is of iron and cobalt approximately in the proportions of the formula Fe_2Co, with from 2 to 6 per cent of silicon, which produces a metal characterized by low hysteresis and high magnetic saturation values. These magnetic advantages increase roughly with the silicon content, and therefore the latter is kept as high as possible without destroying the malleability. Carbon is kept as low as practicable. (1,247,206; Nov. 20, 1917.)

Hans Goldschmidt and Otto Weil of Germany (assignors to Goldschmidt Thermit Co.) patent a method of forming high-percentage tungsten alloys. These are usually produced in electric furnaces, and therefore contain a percentage of carbon, sometimes prohibitive for certain uses. Former attempts by alumino-thermic reactions were unsuccessful, causing large slag losses of the refractory tungsten. Contrary to expectation, good yields by the latter method were obtained by adding indifferent substances to the reacting mixture.

such as lime or fluor-spar, in quantity up to one-quarter of the tungstic oxide used. (Purified scheelite, $CaWO_4$, may evidently also be used.) This process may be used for incorporating tungsten or its alloy into molten metal baths, by merely adding a mixture of ferric oxide, tungstic oxide, aluminium, and lime. The pure ferrotungsten produced immediately alloys without waste, and the easily fusible slag remains liquid on the surface of the bath. The method is claimed to be superior to that of adding pulverized metallic tungsten or ferrotungsten in that no carbon or oxidized impurities are added to the melt, and the waste in non-alloyed tungsten is much reduced. (1,235,969, Aug. 7, 1917.)

Production of Iron Sulphide.—A process for making iron sulphide is patented by N. G. PETINOT of New York City and assigned to the United States Alloys Corporation of New York. One method which has been used is that of heating together, at a high temperature, a mixture of three parts of iron filings and two parts of sulphur in a covered crucible. Another method is to heat together a mixture of iron sulphide and iron filings in a crucible until the whole mass was fused. Still another is that covered by U. S. Patent No. 1,169,093, issued to Mr. Petinot on Jan. 18, 1916, which consists in heating, in an electric furnace, pyrites ore containing silicious or other impurities sufficient to produce a slag, and sufficient iron to form ferrous sulphide according to the following equation:

$$FeS_2 + Fe = 2FeS.$$

The patentee states that while the last mentioned method of manufacture is better than any heretofore employed, he has found that a considerable quantity of sulphur is lost by vaporization, in spite of the protecting blanket of slag, which is formed during the working of the furnace. Moreover, the operation of the furnace is not continuous, because after the charge is fused and the chemical reaction referred to above is completed, the furnace must be tapped so as to draw off the ferrous sulphide and also the slag, and then introduce a fresh charge.

In the present process iron pyrites is used with a mixture of oxide of iron in such proportions that, when the mixture is fused, reaction occurs between its constituents. This reaction is represented by any one of the following equations:

$$3FeS_2 + 2FeO = 5FeS + SO_2$$
$$5FeS_2 + Fe_2O_3 = 8FeS + 2SO$$
$$7FeS_2 + 2Fe_2O_3 = 11FeS + 3SO_2$$

The mixture is, therefore, made up so as to correspond to the reactions given above; the proportions depending upon the analysis of the iron oxide used for the purpose in view. The mixture is fused in an electric furnace preferably of the Siemens type.

When the mixture is fused, the reaction occurs as indicated above, and the iron sulphide (FeS) accumulates in the bottom of the crucible, while the fused mixture of pyrites and iron oxide that still remain in their unreduced condition at the top of the furnace, form a pseudo-slag. When sufficient iron sulphide has accumulated in the crucible, it is tapped without shutting down the furnace. The furnace may also be charged without stopping the process, thus making the method of manufacture a continuous one.

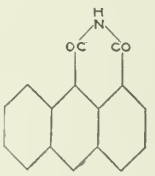
The patent states that while it is true, as indicated by the reactions shown in the equations given above, that sulphur is lost in the form of SO_2, it is to be noted that this sulphur has a useful function as a reducing agent. This sulphur removes the oxygen from the iron oxide, whereas, in the previously mentioned patent, the sulphur is lost by vaporization and, therefore, performs no useful work. (1,252,024, Jan. 1, 1918.)

Dyestuffs

Bluish-Green Vat Dyes.—MICHAEL KARDOS of Charlottenburg, and PAUL NARVIASKY of Ludwigshafen, Germany, patent a process of making certain vat dyes. The patent is assigned to the Badische Anilin & Soda Fabrik. The dyes referred to fall in a class patented under Patent No. 1,216,134, but are not specifically described in that patent. That patent claims the specific coloring matter obtainable by melting anthracene-1.9-dicarboxylic acid imid with caustic alkali, and states that this specific coloring matter yields a cherry-red vat and dyes cotton a beautiful full green. This specific dye apparently possesses an unsubstituted imid group.

The class of coloring matters described in the present patent are characterized by possessing a substituted imid group by giving from red to violet vats with alkaline hydrosulphite solutions and by yielding bluish-green shades on cotton; that is to say, they yield more bluish shades of green than does the coloring matter obtainable from anthracene-1.9-dicarboxylic acid imid.

They can be obtained by subjecting to the action of molten caustic alkali an anthracene-1.9-dicarboxylic acid imid corresponding to the formula



in which the hydrogen of the imid group has been substituted, for instance, by hydroxyl, or alkyl, or aryl. Other methods are also described. (1,253,252, Jan. 15, 1918.)

Miscellaneous Chemical Processes

Alcohol Manufacture.—BURRITT S. LACY of Sewaren, N. J., proposes to produce alcohols of the paraffin series, such as methyl alcohol, by treating alkyl halogens, such as methyl chloride, with hydroxides or carbonates of the alkaline earths. The conditions for the reaction between lime and methyl chloride are given as follows:

"(1) That the methyl chloride gas, the solution and the solid lime be vigorously and continuously agitated together.

"The probable explanation of the necessity of this is that the reaction occurs only in solution, *i.e.*, between the dissolved CH_3Cl gas and the dissolved $Ca(OH)_2$, consequently in order to get the maximum reaction velocity the solution must be kept saturated with the CH_3Cl and $Ca(OH)_2$.

"(2) That the methyl chloride be forced into the reaction vessel at such a rate that the total pressure as registered by the gage of the reaction vessel shall be maintained at a point which is considerably above the vapor pressure of the liquid alone in the absence of methyl chloride. The difference between the total pressure as registered by the gage of the reaction vessel during reaction, and that observed when there is no methyl chloride present, I designate as the effective pressure of the methyl chloride.

"I have found that the rapidity of the reaction, other things being equal, is in direct proportion to the effective pressure of the methyl chloride.

"(3) The temperature should be considerably above 100 deg. C., as the velocity—other things being equal—increases rapidly with the temperature.

The patent is assigned to the Roessler & Hasslacher Chemical Co. of New York. (1,253,055, Jan. 8, 1918.)

Purification of Crude Benzol.—HERMAN B. KIPPER of Muskegon, Mich., proposes to purify crude benzol or light oil by treating it with a caustic soda solution which contains comminuted wood-paper pulp, or other cellulose. The hydrogen sulphide is removed and the carbon bisulphide is also almost completely removed. This is explained probably by the fact that in the manufacture of artificial silk, cellulose fiber, caustic soda and carbon bisulphide react to form the so-called "xanthates," the reaction, according to Cross and Bevan, being as follows:

$$XONa + CS_2 = C\begin{matrix}SOX\\SNa\end{matrix}$$

(X representing the cellulose molecule.)

In carrying out the process, the purifying solution composed of caustic soda and the comminuted wood-paper pulp, or other cellulose, is caused to enter the top of a vessel, and the impure benzol or light oil enters the bottom of the vessel. Owing to the lighter specific gravity of the benzol or light oil as compared with the purifying solution, the benzol or light oil flows upwardly in the vessel while the purifying solution descends, and the benzol or light oil, in passing up through perforated plates, is subdivided into small drops or globules, thereby facilitating the action of the purifying solution. In consequence, the purifying solution rapidly absorbs the carbon bisulphide contained in the benzol or light oil. (1,253,048, Jan. 8, 1918.)

Purification of Potassium Chloride.—A. B. COX of Cherry Valley, N. Y., patents a process for the purification of potassium chloride which is already partly refined. The patent is assigned to the General Reduction Gas and By-Products Company of New York. Commercial potassium chloride obtained from alkali cakes may contain small amounts of sodium carbonate, borax, sodium sulphate, and also sodium chloride, which it is desirable to remove. It is proposed to add calcium chloride or a similar substance to the impure potassium chloride solution, whereby insoluble compounds are formed, except with the sodium and potassium chlorides. Fractional crystallization is then resorted to to remove the calcium chloride, the sodium and potassium chlorides remaining. One proportion of the sodium chloride is usually very small, and may be left in, or further fractional crystallization may be resorted to. (1,252,784, Jan. 8, 1918.)

United Engineering Society Officers.—The following officers were elected for the ensuing year at the annual meeting of the Trustees of the United Engineering Society, held Jan. 24, 1918: President, Charles F. Rand, Member Am. Inst. Mining Engineers; first vice-president, Calvert Townley, Member Am. Inst. E. E.; second vice-president, Robert M. Dixon, Member Am. Soc. M. E.; treasurer, Dr. Joseph Struthers, Member Am. Inst. Mining Engs.; secretary, Alfred D. Flinn, Member Am. Soc. C. E.; chairman Finance Committee, J. Vipond Davies, Member Am. Soc. C. E.

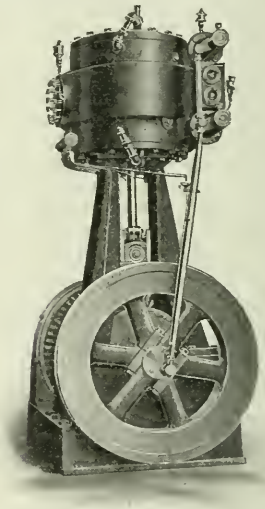
A New Vertical Rotative Dry-Vacuum Pump

A new vertical type of dry-vacuum pump is being manufactured by the Wheeler Condenser & Engineering Company of Carteret, N. J.

The pump shown was recently shipped by the manufacturers for installation in an American navy vessel.

Where much condensing is to be done and where high vacuum is to be maintained, the company recommends installing separate condensate and air pumps. Thus a motor or turbine-driven centrifugal hot-well pump can easily take care of the condensate while this Wheeler dry-vacuum air pump withdraws the air.

As the photograph shows, the inlet valves of this pump are of the semi-rotative type, which are so manipulated by the valve gear as to draw air from the condenser during its full stroke. Clearance difficulties are eliminated in this design of valve gear by providing



GENERAL VIEW OF DRY VACUUM PUMP

ports which register with an equalizing passage. The discharge valves are of the poppet type and are easily accessible, as are the other parts.

The makers state that a motor-driven dry-vacuum pump has numerous other advantages over direct steam drive, among which are: ease of installation; less attention required; no steam pipe radiation losses, and improvement of plant load factor. A few years ago it was argued that motor drive was poor practice because of the long train of elements through which power must pass before reaching the motor—the engine, generator, transmission lines, switchboard, etc.—but to-day shut-down troubles have practically vanished and authorities are strongly recommending motor-driven auxiliaries such as this dry-vacuum pump.

New Officers of American Chemical Society.—President, William H. Nichols, Jan. 1, 1918, to Dec. 31, 1918; directors: H. E. Barnard and George D. Rosengarten, Jan. 1, 1918, to Dec. 31, 1920; councilors-at-large, H. E. Howe, G. A. Hulett, W. A. Noyes, Allen Rogers, Jan. 1, 1918, to Dec. 31, 1920.

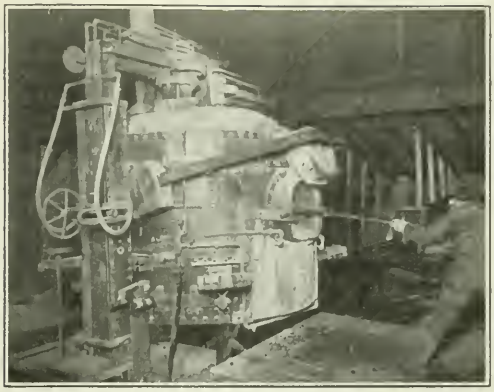
A New Electric Steel Furnace

THE Booth-Hall electric steel furnace shown in the accompanying illustrations was recently placed in operation in the plant of the Midland Electric Steel Company, Terre Haute, Ind. The furnace has a holding capacity of three to five net tons and is supplied by two single-phase transformers of 600 kva. capacity each. The transformers are Scott-connected to the 13,200-volt, 60-cycle, three-phase power line, and deliver current to the furnace at 125 volts secondary. The Scott connection gives a load well balanced over the three-phase primary circuit, as is evidenced by the meter readings. A special switch is provided for cutting the voltage in half when refining or holding heats. The electrodes are automomatically regulated and, by proper manipulation of the electrode regulators and the voltage reduction switch it is possible to put any fraction of full power into the furnace. The furnace operates at about 90 per cent power factor, giving a power input at full load of from 1000 to 1100 kw.

This furnace is built for use on either single, two or three-phase power lines and the furnace itself is built to operate either single, two or three-phase. The single-phase furnace employs an auxiliary electrode, a main electrode, a conducting hearth and a cast-steel grid buried under the hearth. The two-phase furnace employs two main electrodes and two grids, whereas the three-phase furnace employs three main electrodes but only one grid. It is anticipated that the furnace for single-phase operation will be built only in the smaller sizes, as a single-phase load of any considerable size is not acceptable to power companies. Three-phase operation will be employed only in the largest capacities where the increased number of electrodes will tend to facilitate melting down and refining. The two-phase furnace will be suitable under most conditions, and it is with such a furnace that this article deals.

Scrap steel, ranging from machine shop turnings to heavy melting steel, is charged into the furnace. When the furnace is charged the auxiliary electrode and the two main electrodes are let down until they rest upon the scrap. A pawl upon the auxiliary electrode holder is released so that the electrode rests of its own weight upon the scrap and the main electrodes are drawn up, creating an arc under each, the arc being governed by the automatic electrode regulators, assuring a uniform power imput into the furnace and a nicely balanced load in the power lines. This results in heat being generated by the two arcs from the main electrodes to the scrap, while the auxiliary electrode, under which no arc is formed, acts as the common return. By reason of the electrode resting of its own weight upon the scrap, no arc can form under the auxiliary.

When a pool has been formed on the hearth sufficient to make it conductive of electricity, the current begins to flow through the hearth and out through two sets of steel grids embedded beneath the hearth. The fact that this is taking place is immediately recorded by the ammeters, and the auxiliary electrode is then drawn out of contact with the scrap and forms its own seal of the electrode opening in the roof. The furnace then continues to operate as a two-phase



GENERAL VIEW OF BOOTH-HALL FURNACE

furnace, with two independent circuits, the current from one side of each transformer making a complete circuit through one electrode, across the arc, through the bath and the hearth to the opposing grid, and so back to the other side of the transformer.

It is to be noted that the auxiliary electrode is withdrawn before the scrap underneath melts and consequently no carbon is absorbed by the liquid steel from this source.

The advantages claimed for this principle of operation are:

(1) The use of the auxiliary electrode renders the starting of every heat positive and does away with trouble in making contact.

(2) The use of the conducting hearth gives uniform heating of the entire bath, prevents sculls and makes speedier and more thorough distribution of the heavier alloys, such as chrome, tungsten, vanadium, manganese and nickel, which sink to the bottom of the bath.

(3) The use of two independent circuits, crisscrossing in the bath, combined with bottom heating, gives a maximum circulation of the bath.

(4) The use of an auxiliary electrode in combination with a conducting hearth enables the use of a minimum number of electrodes for multi-phase service, since the auxiliary electrode is used only at the very beginning of the heat when conditions are least severe. This results in lower electrode consumption and reduction in heat losses.

(5) The hearth is solid, similar to the open hearth, with no openings or bottom contact to weaken the lining, and is sintered in place, layer by layer, forming a monolithic mass. There is no water-cooling of hearth or grids, and the operation of the furnace has shown that none is necessary.

On an absolutely cold botton it is necessary to employ the auxiliary electrode for about 45 min. before the hearth becomes conductive of electricity. On a furnace that has been shut down over night it requires from 20 to 30 min., and on a hot furnace not more than 10 min. and frequently not at all.

The Booth-Hall furnace is spherical in shape with a saucer-like bottom. The shell is made of ½-in. riveted steel plate. The main electrodes are placed on opposite sides of the furnace and the auxiliary electrode directly alongside of one of the main electrodes and toward the front of the furnace.

The furnace may be lined either basic or acid, the unit at Terre Haute being lined basic. The hearth is 24 in. thick and the grids are 18 in. below the top of

the hearth. The furnace hearth is composed chiefly of either magnesite or dolomite and is solidly sintered in, layer on layer. From the hearth up the walls are made of brick, the first three rows which reach above the slag line being made of magnesite brick and the rest of silica brick. Silica brick are employed for the roof.

The furnace door is of improved design, consisting of a door with open back to which is attached two yokes, each counter-weighted. The yokes extend part way from the door toward the sides of the furnace and by reason of the counter-weights the door can be raised with one hand by the furnace operator. The door is built in with brick, the open back allowing radiation of the heat and preserving the brick. The door pivots on the yokes as it is raised and lowered, keeping the hot inner side always to the furnace wall. The door is oval in shape so that there is no tendency to breast up the opening, as is done where round doors are employed and there is, therefore, maximum charging space. It is possible to raise the door as far as

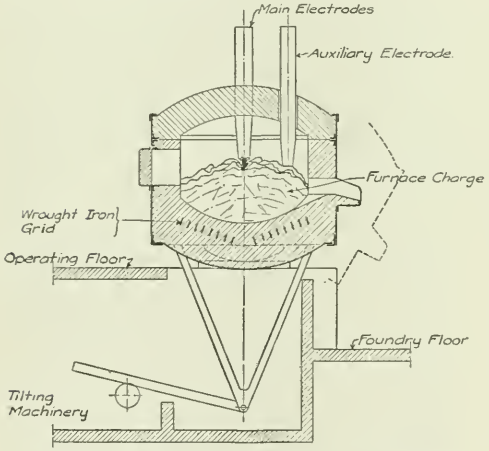


FIG. 1. DIAGRAMMATIC LAY-OUT OF TWO-PHASE FURNACE

required so that for looking into the furnace for rabbling or for taking out test ladles, the entire opening does not have to be employed. The door comes down flush against the door frame, preventing heat losses from the furnace and also the seeping of air into the furnace to disturb the furnace conditions. The door frame is made in two sections, one of which extends across the top and can be readily replaced when burnt out.

By placing the door in the rear of the furnace changing and slagging operations are simplified. By tilting the furnace forward it is possible to change the furnace quickly by the use of a hopper arrangement similar to that used for charging concrete mixers. By tilting the furnace backward it is possible to bring the slag flush with the door sill, either for rabbling or for pouring it off into slag pots. It is also practical to pour fluid slags over the charging spout.

The furnace is tilted by a very simple arrangement of rockers, structural steel struts and reducing gears. The rockers are placed under the furnace in such a way that there is no possibility of material falling on the guides and interfering with the tilt. The furnace tilts backward as well as forward, so that it is possible to bring the slag line flush with the door when slagging from the furnace, making slagging a speedier operation and easier on the furnace men.

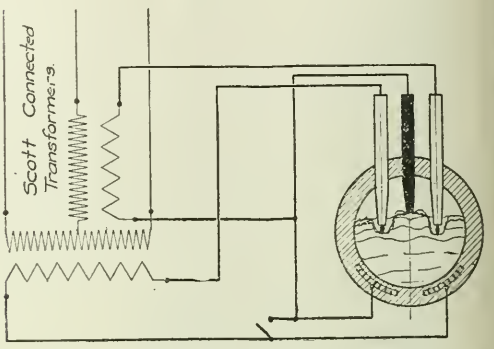

FIG. 2. ELECTRICAL CONNECTIONS FOR TWO-PHASE FURNACE

The electrode clamps are of an improved construction which allows of clamping or releasing the electrode by turning a lever at the edge of the furnace and does away with necessity of the operator climbing on the furnace roof. Each segment of the electrode clamp is water-cooled. The electrode holders are of rugged construction, each being capable of holding 10 tons at the end. Magnetic circuits are broken up by a special construction.

It will be noted in the accompanying illustrations that no electrode water cooling collars are shown in the roof, due to the fact that the temporary arrangement of three electrodes in each holder is used, and it has been found difficult to make a practical collar under the circumstances. The design of the furnace calls for a special type of electrode collar, which fits

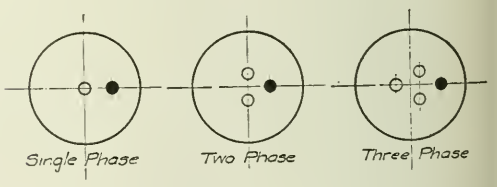

FIG. 3. RELATIVE LOCATION OF MAIN AND AUXILIARY ELECTRODES IN SINGLE, TWO AND THREE-PHASE FURNACES

around each electrode, extending well down into the roof brick, providing further protection for both the electrodes and the roof arch at this point. Differing from other types of electric furnaces, the Booth-Hall has provided not only water-cooling collars around the electrodes, but water-cooling in the electrode clamps themselves.

The Booth-Hall electric steel furnace was originated by William K. Booth, and its mechanical design carried out by Julius R. Hall. The furnace is manufactured by the Booth-Hall Company, Chicago, Ill.

Book Reviews

COAL TAR AND AMMONIA. By *George Lunge, Ph.D.* Fifth and enlarged edition. 1658 pages. Price, $18. New York: D. Van Nostrand Company.

No book could come more opportunely at this time than this most comprehensive compilation of information regarding the most vital subjects of coal tar and ammonia.

With true European thoroughness every possible scrap of information relative to these matters has been brought together, often it seems without a sufficient amount of discrimination.

Processes and patents that have never even got beyond the paper stage are placed side by side with those that are the foundations for world industries, thus making it hard for the non-expert to discriminate with intelligence.

The first two volumes discuss at length and in considerable details not only the different methods of obtaining coal tar, but also the fractionation of the different constituents and the products obtainable from these.

The third volume discusses ammonia, and should be carefully studied by all those who to-day advocate the installation of a government nitrogen fixation plant.

The many means by which ammonia can be obtained from various waste products now going to waste in the United States is made apparent even by a cursory glancing through this volume.

The references occurring all through the three volumes are up to the very latest date.

It really goes without saying that these last volumes by Dr. Lunge are standard and are another monument erected by him to applied chemistry.

FINDING AND STOPPING WASTE IN MODERN BOILER ROOMS. By *Engineers of the Harrison Safety Boiler Works.* Cloth, 9 in. by 7 in., 276 pages, 213 illustrations. Price, $1.00. Philadelphia: Harrison Safety Boiler Works.

The saving of coal is the purpose of this handbook, which is addressed to power plant owners, managers, engineers and firemen. The preface states that such statements, tables, charts, etc., have been selected as were supported by experiments and tests, references being given wherever possible to the original authorities. The book is divided into five sections under the following headings: Fuels, Combustion, Heat Absorption, Boiler Efficiency and Boiler Testing, Boiler Plant Proportioning and Management. It is illustrated and conveniently indexed and discusses theory and practice under each heading. The compilation was made by George H. Gibson, assisted by Percy S. Lyon, now a captain in the Coast Artillery. The book contains a large amount of very useful information for anyone connected with or interested in power plant work.

* * *

TESTING FOR THE FLOTATION PROCESS. By *A. W. Fahrenwald.* Pocket size, 4 in. by 7 in., 173 pages, 34 illus. Price, $1.50. New York: John Wiley & Sons, Inc. London: Chapman & Hall.

This work is a compendium in handy form of a variety of data and information that will be useful to the metallurgist. The author has not introduced many personal ideas, but has drawn widely and freely on excellent sources of information. In this respect the book represents a condensation of the best literature, with references enabling anyone to pursue the subject further. In order to make tests intelligently it is necessary to understand fundamental principles. Hence the greater part of the book is devoted to a discussion of the physics and chemistry of flotation and the materials used in the process. The subject of colloids is clarified and condensed sufficiently to give the reader a sound idea of its relation to flotation. In like manner surface tension, capillarity, osmosis, viscosity and emulsification are discussed. Oils, addition agents and the use of sulphidizing agents receive ample consideration. When all these subjects are covered, the author devotes a chapter to tests, and discusses the effect of method of grinding, fineness of grinding, kind and amount of frothing agent used, temperature, acidity or alkalinity, varying speed of agitation and effect of addition agents. A chapter on appropriate formulas and tables completes the book.

THE LIFE OF ROBERT HARE, AN AMERICAN CHEMIST. By *Edgar Fahs Smith.* 508 pages. Price, $5.00. Philadelphia: J. B. Lippincott & Co.

The Provost of the University of Pennsylvania, better known to chemists as Prof. Edgar Fahs Smith, has made a distinct contribution to the history of modern science in this beautiful volume. Robert Hare lived in Philadelphia at a time when, as Dr. Smith says, science flourished as nowhere in America. He was born in 1781. Benjamin Franklin was still living, Joseph Priestley came later from England, James Woodhouse, fresh from the inspiration of Lavoisier, was his teacher and adviser, and these were also the days of Sir Humphrey Davy and Volta and Berzelius. With Faraday he had a long correspondence. There were giants in those days.

The Life is divided into three periods, of which the first was from his birth to 1818, or until he was thirty-seven years old. This covers the time of his study at the University of Pennsylvania, the beginning of his life-long friendship with Benjamin Silliman, and the period of his activity as a business man, during which time he never ceased to work in his private laboratory and to address himself to the study of science. His father, an Englishman by birth, who achieved prosperity by brewing porter, gave his son a sound classical education, and throughout his abundant years we find constant indications of his native and cordial familiarity with the graces of life. He succeeded his father in the administration of the affairs of Hare's brewery until near the close of the first period. In 1816 he received an honorary doctorate of medicine from Harvard College, and in 1818 he was appointed to the chair of chemistry at the school of medicine of the University of Pennsylvania. This he filled with great usefulness and distinction until his voluntary retirement in 1847, when the trustees conferred upon him the title of Professor Emeritus. He died in 1857.

He discovered the oxy-hydrogen blow-pipe. This is distinctly his invention, which he developed as a young man, shortly after leaving the University. With it he was able to melt platinum, and years afterward one of his pupils, J. Bishop, founded the platinum industry at Malvern, Pennsylvania. Another application of his discovery was the limelight, the Drummond light, so called, which gave the first powerful illumination for lighthouses. As early as 1822 he used a cathode of mercury in an aqueous electrolyte, and then and there was born the idea which led to the production of caustic soda from salt by the use of a mercury cathode in our own time. Not long afterward he brought out Hare's deflagrator, which was, in fact, a mobilized voltaic pile. Powerful deflagrators were in common use in America long before any apparatus of equal efficiency was known in Europe. Faraday declared it to be the most perfect form of the apparatus then known, and he acknowledged Hare as the inventor, although he had, at a later date, devised a voltaic trough to meet his needs that was the same in principle. Hare's calorimeter was another contribution. He originated important steps in gas analysis and he was a pioneer in the development of endometers. In 1839 he devised an actual electric furnace in which he isolated calcium, prepared calcium carbide which gave him acetylene (but which he did not recognize), and converted amorphous carbon into graphite. It was all primitive and crude, but here is the record! These are but a fraction of his contributions.

It is a book that should be in the library of every chemist who is of scholarly disposition. Correspondence, especially with Professor Silliman, fills a large part of the volume, and it is not always easy reading, because the literary habits of men of science have changed. He did not make drawings of his apparatus, he described them, and we are so accustomed to getting our ideas from drawings and so unused to descriptions without drawings to help us that the tax upon the memory while reading is unwonted and so seems severe. His language, nevertheless, was de-

lightful, and while he was a bit disputatious, it was always because of his convictions and his earnest effort to approach the truth. He was not satisfied with the distinctions between acids and bases as taught, and his views, which are presented at length, are of marked interest. He was a careful and exact thinker and a reading of this book leads to the conclusion that the progress of chemistry would have been helped by a livelier memory of the contributions of Robert Hare. We felicitate Professor Smith on his accomplishment and are thankful for the record.

* * *

SULPHURIC ACID AND ALKALI. By *George Lunge, Ph.D.* Supplement to Vol. I, Sulphuric and Nitric Acid, 4th Ed. Octavo (14 x 22 cm.), 347 pages, 25 cuts. Price, $5.00 net. New York: D. Van Nostrand Company.

Intended to supplement the 1913 edition by adding a complete record of all subsequent improvements in the art, and incidentally to save the purchasers of the 1913 books from having to buy an entirely new edition in order to get this recent literature. It looks as if the final solution might be found in resolving the treatise into a "Yahrbuch," thus bringing everyone interested up to date annually. The index includes both the subject matter of the original Volume I and of this supplement. The chapters correspond to those of the original volume, and each article is referred to the page where it fits into the earlier text. An immense amount of valuable literature is thus made available and accessible. The only criticism we have to offer is that many visionary statements and patent claims are reproduced without comment, giving to the book, in places, the character of a mere compilation rather than a treatise wherein the author is guide and mentor.

Personal

Mr. ROBERT J. ANDERSON, late chief chemist for the Cleveland Metal Products Co. is now engineer of tests of ordnance material, War Department, and is stationed at the Brier Hill Steel Co., Youngstown, Ohio.

The partnership of Falkenburg & Laucks, of Seattle, Wash., has been dissolved effective Feb 10, 1918. Mr. M. J. FALKENBURG has organized a company to be known as Falkenburg & Co., analytical and consulting chemists, Second and Yesler Sts., Seattle, Wash. Mr. I. F. LAUCKS has also established a separate business as chemist and metallurgist at 99 Marion St., Seattle.

Mr. RUSSELL T. GRAY, formerly advertising manager of the Haynes Automobile Company and more recently secretary of the Shuman Advertising Company, has opened an office in the First National Bank Building, Chicago, as an advertising engineer in the technical field.

Mr. ELLWOOD HENDRICK of New York City has allied himself with the staff of METALLURGICAL AND CHEMICAL ENGINEERING as Consulting Editor. For some time past Mr. Hendrick has been an occasional editorial contributor to this journal, and his intimate familiarity with phases of our rapidly growing chemical industry will assist us materially in reflecting conditions in that important branch of the field to which our pages are devoted.

Mr. A. G. MCGREGOR, who erected the International, Calumet & Arizona, Verde Extension and other reduction works in the Southwest, has returned to Arizona from New York and is expected to sail at an early date for Chile and Peru with representatives of copper interests.

Mr. WILLIAM PIGGOTT of Seattle, Wash., president of the Seattle Car & Foundry Co., and vice-president of the Pacific Coast Steel Co., has been placed in charge of wooden shipbuilding for the United States Shipping Board in the Seattle district. Mr. Piggott will succeed Capt. J. F. Blaine, who will retain charge of the steel ship construction.

Dr. CHARLES L. REESE, Chemical Director of the E. I. du Pont de Nemours Co., has been elected chairman of the Philadelphia Section of the American Chemical Society. Dr. Reese was recently elected a director of the du Pont Company.

Mr. S. S. SADTLER of Philadelphia was in New York on business during the first week of February.

Mr. WILLIAM WRAITH, general manager of the International Smelting Company has gone from Salt Lake City to New York to assume additional duties as vice-president of the Andes Copper Mining Co. Mr. Wraith expects shortly to make a trip to South America in connection with plans for development of their low-grade copper deposits at Porterillas, Chile. O. M. KUCHS, since 1913 superintendent of the Tooele smelter of the International Smelting Co., has assumed the position of assistant general manager with headquarters in Salt Lake City, while A. B. YOUNG, superintendent of the blast furnace department has been made superintendent of the smelting plant.

Current Market Reports

The Iron and Steel Market

The iron and steel industry has felt practically no results from Fuel Adiminstrator Garfield's fuel conservation order. There has been practically no ultimate loss of production, as the blast furnaces were permitted to operate and any pig iron accumulated can either be used in steel production or be set aside as a convenient reserve. Transportation conditions have not been improved, but it is conceded in most quarters that had it not been for the fuel order they would have become still worse.

PRODUCTION LIGHTER

Blast furnace operations have been still lighter, the past two or three weeks seeing the smallest production of pig iron in this whole period of restricted operations. Apart from the general railroad blockade there have been particularly bad weather conditions in the Connellsville coke region, and not only have coke receipts at furnaces been very light, but pig iron production in proportion to coke has been particularly light. Many furnaces, through frequent bankings, have been showing a coke consumption of 2800 to 3000 lb. per ton of pig iron. Many furnace managers are making a careful effort to anticipate coke supplies and operate their furnaces with correspondingly light blasts, so as to insure regular and continuous operation, no matter how light the output. One furnace manager claims to have operated for a considerable period with an output 50 per cent of normal, yet with a coke consumption of only 2400 lb.

The blast furnaces of the Central West depending upon Connellsville coke have been producing an average of 25 to 40 per cent of their capacity in pig iron. Blast furnaces depending upon by-product coke have done much better, possibly 75 per cent. The difference is not in transportation conditions in general, but that the Government favors the movement of by-product coal, not on account of the coke it produces, but on account of the by-products. In other words the real condition is that the coke is the by-product and the toluol, etc., the product. One recalls the time when the first Gary blast furnaces were put in operation, not so much for the purpose of supplying pig iron as for the purpose of supplying gas for the first run of the steel department. The pig iron could be secured elsewhere, the gas could not.

While the supply of pig iron is thus very much restricted, the ability of mills to ship finished steel is at least equally restricted, and it is a question whether steel mill operations as a while are being limited the more by shortage of raw material or inability to dispose of finished product. There is practically no storage capacity left in mill warehouses or yards, and production in nearly all finishing departments is regulated by car supplies and permits to ship. Unfortunately these two necessary elements are not always synchronous. One may load steel and wait for a permit, paying demurrage meanwhile, or seek a permit first and then see its time limit pass while one is waiting for cars.

Shipments of finished steel products from mills in the past fortnight have averaged somewhat less than 60 per cent of capacity. This means more than 60 per cent of the output in 1916, as while the mills operated full in that year, the capacity at present is much larger, by between 10 and 15 per cent. Fully two-thirds of the shipments have been of war steel, leaving commercial shipments at not more

than 20 per cent of capacity. Not all war steel on order is possible of shipment, however, there being various restrictions in that quarter also.

Despite the fact that steel receipts by ordinary commercial consumers are only about 20 per cent of the productive capacity, there is no particular complaint, as to shipments, on the part of buyers. There operations are equally restricted by the transportation situation.

The Outlook

The iron and steel industry has nothing but an outlook. There has been no market for weeks past, and there will be no regular market until the transportation situation has been loosened up and the business of making and consuming steel, at something like a normal rate, can be resumed. Presumably the backbone of winter has been broken, and the common view in the trade is that the effectiveness of the railroads is going to be greatly increased by the advent of respectable weather, the chief menace now being that of floods. The congestion may clear rapidly, but in all probability the clearing will be sporadic geographically, and that may introduce fresh complications. That the steel industry will follow closely upon the heels of the railroads is certain. As transportation conditions improve steel production will at once increase.

There is very little attempt to speculate what will be done or will not be done at Washington against the date, March 31, to which the set prices were continued by the President's announcement late in December. A great deal can occur, as to consumption and production, before that time. The question of costs, so much discussed in the late months of last year, is a dead issue. There are no costs, according to the common view of costs. There is simply a total of expenses, made up in altogether unusual manner, and a total of tons that chanced to be shipped. Dividing the one by the other means nothing as to next week or next month.

The Navy Department's experiment of inviting competitive bidding on the purchase of a variety of steel products is an interesting departure. Hitherto the placing of orders has been in the form of allotments, the set prices being taken as a matter of course. The competition has resulted in some prices being made, chiefly for manufactured steel such as rivets, nuts and bolts, etc., at materially lower than the set prices. Doubtless Washington will be disposed to carry the experiments farther. As a buyer the Government has an advantage at the moment it does not ordinarily enjoy. Government red tape is as objectionable as formerly, but there is the great distinction that if one has a Government order his chances of being able to ship the material are very much greater than if the order is for ordinary commercial steel.

Thus the main outlook the iron and steel market has at this writing is that within the next few weeks there are likely to be physical and other developments of fundamental importance, that will furnish a basis on which the future of tonnage and prices can be considered.

Non-Ferrous Metal Market

Friday, Feb. 8.—Conditions are unchanged in the copper market with inactivity prevailing. Tin is just as scarce and is higher. Lead is dull but remains firm. Spelter is still dull and somewhat unsettled.

Tin—Supplies of spot tin of any size are hard to locate and no Straits tin is offered for sale. Arrivals in January were less than 2000 tons, and so far this month 175 tons have arrived with 5350 tons reported afloat from the Straits. *The American Metal Market* says: "The combination of a further advance abroad, heavy inquiry here, and the non-receipt of private offers have caused an extremely strong market and there is greater irregularity than ever between different sellers' prices, some having practically withdrawn from the market in anticipation of further advances.

"Some values in various positions are approximately as follows:

"Ninety-nine per cent quality for delivery in a week or so at 78c. per pound.

"Banca tin on steamer actually afloat at 73.50c.

"Banca tin February shipment from Batavia at 70c.

"Banca tin March shipment from Batavia at 69.50c."

Copper—Better weather conditions are expected to relieve the transportation situation and to afford relief in the way of supplies of matte and blister copper for the Eastern refineries. The market is comparatively dull and unchanged at the Government price of 23.50c. for producers and 24.67½c. for jobbers.

Lead—The trust price in New York remains at 6.75 with outsiders asking 7c. as a minimum. The St. Louis market is around 6.80c. Supplies are not large, owing to the railroad congestion, but better weather is expected to afford relief.

Spelter—The market continues quiet. No price has yet been fixed for Grade A, although numerous rumors were around that 12c. had been agreed upon. Prime Western is held at 8c., New York and 7.75c. at St. Louis.

Tungsten—Scheelite is offered at $30 by California producers but no sales are reported at that figure. Importers report the nominal price of $26 for scheelite and $20 to $26 for wolframite. Tungsten, molybdenum, vanadium, manganese, chrome and ferro-alloys come under the license authority of the American Iron and Steel Institute in so far as these ores are imported from abroad. Importer dealers and consumers are henceforth required to give a guarantee before shipments are released to them.

Molybdenum—Charles Hardy reports considerable activity in molybdenite at $2.15, basis 85 per cent. Arrivals in the East have lately increased but have been readily absorbed.

Quicksilver—California virgin is quoted at $130 with Mexican at $120.

Chrome—Ore is still scarce and higher.

Other Metals

Aluminium, lb.	.36–.38
Bismuth, lb.	2.50–2.75
Cadmium, lb.	1.50
Nickel, electrolytic, lb.	.55
Silver, oz.	.86⅛
Platinum, oz.	105.00
Palladium, oz.	130.00–135.00
Cobalt, lb.	3.25–3.50
Magnesium, lb.	2.00

Chemical Market

Coal-Tar Products: Quiet prevailed in this situation during the interval. Transit conditions, as well as the inability of plants to secure sufficient coal to operate up to regular schedule, tends to restrict operations. With the government taking over several of the important items the trade is evidently delayed in acclimating itself to the new conditions created.

Benzol: While there are more contracts being closed over the next few months than for some time heretofore, there are not many contracts being closed over the entire year. Spot supplies are plentiful and prices are low.

Phenol: There is but little material offered at this time. The government has contracted for practically all the material to be produced for some time to come.

Toluol: Several dealers have succeeded in securing material which has been selling at fancy prices, but the government is following up the matter and has seized several lots in the past few days.

Naphthalene is not active. Both buyers and sellers appear to be giving the matter but little attention. Prices are unchanged.

Aniline Oil has been advanced in price because of the scarcity and high prices of the necessary acids.

Aniline Salt is fairly firm with low offerings absorbed and producers quoting an advance of a cent or two.

Dimethylaniline: The demand is quiet, but offerings are light and prices are fairly well maintained.

Diethylaniline: There are but few producers of this material and offerings are so light that quotations are nominal.

Diphenylamine: This material is in heavy demand by explosive manufacturers, and there is practically none available in the open market.

Benzoate of Soda is held in speculative hands, with producers sold up and prices fluctuating over a wide range.

Saccharine. Surplus quantities are flooding the market because of the falling off in the export demand, and prices have been reduced by more than 50 per cent.

Salicylic Acid: With a heavy output and only a routine demand a break in price has resulted.

Para Nitro Phenol: The production is restricted to a few quarters ; the demand is fair and prices are well maintained.

HEAVY CHEMICALS.—As a result of the freight embargoes and the order of the fuel administration there has been a gradual readjustment of chemical values. Buyers, owing to the uncertainty of deliveries, have not shown any particular desire to purchase for shipment from works. There has however been a gradual improvement in the demand for spot lots and for material at near-by shipping points, and these offers have generally commanded a premium. As a result of greatly restricted shipment during January bills of lading of that month are in particular demand in order to carry out contracts to the letter.

Caustic Soda: From a product highly speculative the movement in caustic has been of such minor consequence that many items other than this have shown more activity. During the early weeks of January there was practically no activity noted. As the movement closed it was apparent that January shipments from works were very meager, and those who had sold actual January shipment now find a market of approximately 6.40 for these bills as against 5.45 for February shipment. For shipment, March sales have occurred at 5.35, but this price is low. Producers are not inclined to go much below 5.50 for any position up to June.

Soda Ash: There has been a very urgent request for prompt ash in barrels, and it is apparent export permits have been granted for important amounts. Barrels have sold as high as 3.45, and at the moment there is practically no material available in New York in this package. Bags have not been in such urgent request, and the market remains at about 3c. for spot and from works. Dense ash continues scarce and single bags are held at 3.85 barrels and double bags at 4c.

Sulphuric Acid: Considerable acid has appeared on the market during the interval, not due to any increased output but to the fact that acid has backed up on producers, who have found it difficult to ship in face of the embargoes. Tank cars are so scarce that much acid that would be otherwise bought remains at producing point owing to lack of carrying room. Sixty-six-degree acid has been available at prices ranging from $38 to $42, seller's tanks, works. For export there has been considerable business passing in drums at $90 f.a.s., drums included. Sixty-degree acid has been offered at $32.50 works, seller's tanks.

Muriatic Acid: The product continues scarce. Practically no test other than 20 is offered. Weak acid does not attract a buyer, and in view of the high prices obtained for the 20-deg. manufacturers see no profit in concentrating to 22 deg. Contracts have been offered of 20 deg. at 2.50 to 2.65 works, car quantities.

Nitric Acid: Off-colored material has been available at 9c., but pure white acid 42 deg. is held at 9½ to 10c. works.

Cyanide of Soda: There has been more activity noted and prompt material has sold at 43½c., although at the moment of writing there are lots available at 42c.

Copper Sulphate: Both Nichols and A. S. & R. brands have been offered by second hands at prices ranging from 8.70 to 9c. Sales have occurred in fairly large quantities at 8⅞c., and the second-hand market has been fairly well cleaned up. Nine cents is now a good price from second hands. Producers are quoting 9½c. All prices are for 99 per cent large crystals, prompt shipment.

Bichromates: The spot market has again developed into a speculative one, and there is again evidence of manipulation. Spot lots have generally commanded considerable attention and sales have occurred at from 20c. to 24c. From works sellers quote 22c. to 24c. and even higher for late deliveries. The potash material has been neglected and there have been actual offers at 41c.

Chlorate of Potash: The American producers have seemingly gone after the Japanese producers with a big stock. Although for domestic consumption 40c. to 42½c. are the lowest prices obtainable for export, 35c. and 36c. have been named with the broad intimation that even lower prices would be considered if necessary. For domestic business a resale occurred at 36c., but aside from this there does not appear to have been much business undr 40c. Japanese material has sold at 35c. and 36c. rolling to New York

Sodium Sulphite: Prompt stocks have been about eliminated from the market. For March shipment there are sellers of the 99/50 per cent moisture at 5c., New York.

Sodium Sulphide: Spot values have advanced to 5c for the 60/62 per cent fused. From works sellers quote 4¾c. to 4⅞c.

Hydrosulphite of Soda: There are offers of the powdered at $1.45 and a 10 per cent liquid is offered at 6½c.

Hyposulphite of Soda: Spot lots have changed hands at 2½c., and contracts are available at 2c. works for tanners' size. Pea size is held at approximately ½c. higher.

Prussiates: The sodium salt has been very scarce, and spot values have advanced to 37½. The yellow potassium salt has been somewhat easier and there are supplies available at $1.22½.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, FEB. 7, 1918

Acetic anhydride	lb.	1.35 — 1.50
Acetone, drums	lb.	Nominal
Acid, acetic, 28 per cent	lb.	.05½— .06
Acetic, 56 per cent	lb.	.11¼— .12
Acetic, glacial, 99½ per cent, carboys	lb.	.34 — .35
Boric, crystals	lb.	.13¼— .14¼
Citric, crystals	lb.	.75 — .78
Hydrochloric, C. P	lb.	Nominal
Hydrochloric, 20 deg	lb.	.02½— .03
Hydrochloric, conc., 22 deg	lb.	.03 — .03½
Hydrofluoric, 30 per cent, in barrels	lb.	.06 — .06½
Lactic, 44 per cent	lb.	.15 — .15½
Lactic, 22 per cent	lb.	.05½— .06½
Nitric, 36 deg	lb.	Nominal
Nitric, 42 deg	lb.	.09½— .09½
Oxalic, crystals	lb.	.45½— .46½
Phosphoric, 47-50 per cent crude	lb.	.07½— .08
Phosphoric, ref. 50 per cent	lb.	.26 — .....
Picric	lb.	Nominal

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

THE ALL-STATE CHEMICAL MANUFACTURING COMPANY, New York. Nominal capital, $5,000. To engage in the manufacture of chemicals and allied products. Incorporators: W. Graveur, D. E. Hubener, and F. J. Nice, 525 West One Hundred and Sixty-ninth Street.

THE ALTREN COMPANY, Chicago, Ill. Capital, $10,000. To manufacture chemical preparations. Incorporators: Charles F. Brandel, James M. Rainey, and Walter Bashong, all of Chicago.

THE AMERICAN LEAD BURNING COMPANY, Inc., New York. Capital, $25,000. To engage in a general lead burning business, and manufacture chemical apparatus of various kinds. Incorporators: W. H. and E. D. Simonson, and G. W. Winans, 210 Parkside Avenue, Brooklyn.

THE ATLANTIC POTASH CORPORATION, Dover, Del. Capital, $1,000,000. To manufacture potash and chemical compounds.

BRANDON, HADGES & MCLAIN, New York. Capital, $20,000. To manufacture metallurgical supplies, graphite and carbon. Incorporators: A. C. Head, H. M. Eisenberg, and E. M. James, 2 Rector Street.

THE BROWN SAAL COMPANY, New York. Capital, $10,000. To engage in the manufacture of chemicals and allied products. Incorporators: W. C. Murphy, D. H. Cory, and J. E. Saal, 21 West Forty-sixth Street.

THE BURNS CARTRIDGE MANUFACTURING CORPORATION, Dover, Del. Capital, $500,000. To manufacture cartridges, etc.

THE CENTRAL SMELTING & REFINING WORKS, Inc., Bronx, N. Y. Capital, $50,000. To manufacture smelting and refining metals, etc. Incorporators: S. S. Paymer, J. L. Paymer, and N. Sacks, One Hundred and Thirty-seventh Street and Rider Avenue.

THE CHEMICAL CLAY PRODUCT COMPANY, Daisy, Tenn. Capital, $50,000. To manufacture chemical clay products. Incorporators: L. E., B. M. Hood, and G. S. Keeling.

THE SUPERIOR LEAD & ZINC COMPANY, Kingfisher, Okla. Capital, $150,000. To mine for lead and zinc. Incorporators: Luther V. Smith, S. Scott aand M. W. Hinch.

THE TENNESSEE BAUXITE COMPANY, Hixson, Tenn. Capital, $10,000. To develop bauxite mines estimated to contain about 500,000 tons of aluminum ore and install a drying and concentrating plant. Incorporators: C. W. Fisher, R. H. Hunt, and S. O. Bankson.

THE THOMPSON-WEIMAN COMPANY, Cartersville, Ga. Capital, $600,000. To mine for iron. W. J. Weinman is the principal incorporator.

THE TOPPER BROTHERS IRON COMPANY, Columbus, Ohio. Capital, $200,000. To operate a local iron works. Incorporators: L. L. Goldberg, S. Ornstein, Eugene Morgan, and I and M. Topper.

THE UNIONTOWN FOUNDRY COMPANY, Uniontown, Pa. Capital, $10,000. To operate a local plant. E. R. Floto is the principal incorporator.

THE UNITED STATES SANITARY PRODUCTS CORPORATION, Chicago, Ill. Capital, $100,000. To manufacture chemical compounds, etc.

THE UNITED STATES SMELTING FURNACE COMPANY, of Belleville, Ill., has been incorporated with capital of $50,000 to manufacture and sell smelting and melting furnaces and to smelt and melt ore and metals of all kinds.

THE VALVELESS FLUSH COMPANY, Wilmington, Del. Capital, $300,000. To manufacture flush tanks and devices, etc. Incorporators: F. L., M. E., and L. F. Mettler, Wilmington.

THE WEST COAST GLASS COMPANY, Los Angeles, Cal Capital, $100,000. To manufacture glassware of various kinds. Incorporators: H. R. Jones, Frank C. Ford, Arthur White, G. H. Bessemyer, and R. D. Tiffany

THE WHITNEY MACHINE COMPANY, Winchester, Mass. Capital, $100,000. To manufacture machinery. Incorporators: Arthur E. Whitney, Robert F. Whitney, and Walter C. Goddard, Winchester.

Construction and Operation

Alabama

BIRMINGHAM. — The Connors Steel Company, recently incorporated with a capital of $300,000, is planning to take over and operate the plant of the Woodlawn Rolling Mill, which has been operated by the president of the new company, George W. Connors. The plant will manufacture steel hoops, bands, bars, channels and other steel products.

TALLADEGA.—The Graphite Mills Company has recently taken over the plant and property of the Enterprise Graphite Company, and is planning for the construction of a large new mill on the Hurst property in Clay County to provide for increased capacity. The entire plant of the company will also be removed to this location.

Arizona

BISBEE.—The Copper Queen Consolidated Company is planning for the construction of a large new concentration mill near Warren for the handling of the sulphide taken from Sacramento Hill. At this point there is an immense deposit of the sulphide and the company has started steam shovel stripping.

JEROME.—The United Verde Extension Mining Company is making rapid progress in the construction of a new 1600-ton smelter, the entire works being estimated to cost $3,000,000. The company has also commenced construction of a 12,000-foot tunnel in the Verde Valley for haulage from its mines.

KELVIN.—The Ray-Hercules Copper Company, Ray, is rushing to completion the erection of a large new local copper mill, which will cost, when completed, about $2,000,000.

BISBEE.—The Superior & Pittsburgh Mining Company is planning for the construction of a large new mill at its local properties for the handling of silver-lead ores.

TUCSON.—Roos & Tovote have recently acquired the smelter at Socorro, New Mexico, and are planning for the immediate dismantlement of the plant and shipment to its local works, where it will be utilized as a custom plant, with daily capacity of from 250 to 300 tons of ore.

YUMA.—Operation has been inaugurated in the new concentration mill recently completed at the Red Cloud mine, about forty miles north of Yuma. The mill is of 300 tons capacity, and is equipped with Hendy crusher, Eggleston ball-mill, and three Stebbins dry-concentrating tables. Cris Engle is superintendent.

YUMA.—The Carmelita Mining & Milling Company has commenced the installation of considerable new equipment at its local properties, including hammer-drills, gasoline hoist, Ritz air-compressor, ball-pulverizer, three concentrating tables, and flotation process. The company is planning for extensive development of the seventeen claims which comprise its property. J. A. Marx is superintendent.

Arkansas

KINGDON SPRINGS.—E. N. Stanfield, Oklahoma City, Okla., has recently acquired the Monkey Hill zinc mines, and is planning for extensive development.

California

BAY POINT.—The Pacific Electro Metals Company has contracted with the Great Western Power Company, San Francisco, for supplying power for the operation of the first unit of its new chemical plant now in course of construction. About 4,000 kw. will be necessary for the initial unit.

LOS ANGELES.—The American Can Company is planning for the early construction of a large new plant for the manufacture of cans. The project is estimated to cost $1,000,000, and when completed and in operation the new works will have a capacity of about 3,000,000 cans daily, and will give employment to about 1500 hands.

LOS ANGELES.—The Union Oil Company has commenced the construction of the first unit of its new refinery at Los Angeles Harbor for the manufacture of lubricating oils, gasoline, kerosene, and other petroleum products. When completed the plant will cost about $2,000,000.

LOS ANGELES.—The Warman Steel Casting Company, Douglas Building, manufacturer of electric and crucible steel castings, has awarded a contract for the construction of a new 100-foot addition to its plant. The company is planning to double the capacity of its plant at Huntington Park.

INGOT.—The Afterthought Lead & Zinc Mining Company has recently completed the construction of a large new oil flotation plant, and operations will be inaugurated at an early date. The ore is subjected to two flotations—the first removes the sulphide from the gangue, after which this concentrate is roasted and again floated, when the zinc is separated from the copper. The company is planning for the erection of twenty cottages at the mine for the convenience of its employees. George L. Porter is president; J. T. Robertson is general manager.

KESWICK.—The Mountain Copper Company is planning to double the capacity of its oil-flotation plant at Minnesota station, near Keswick. The enlarged plant will have a capacity of about 1000 tons of ore daily.

OAKLAND.—The Occidental Chemical Company, which is a reorganization of the kelp reduction business of the California Chemical Company, Summerland, is planning for the establishment of a large new plant.

TAFT.—The Richfield Oil Company, which recently acquired the plant of the Phoenix Refinery Company, Bakersfield, is said to be considering the construction of a large new local compressor plant for the extraction of gasoline from high gravity oil.

Colorado

CLIMAX — The Molybdenum Products Company is making rapid progress in the construction of a new mill for the handling of molybdenum taken from its holdings. The company is also planning for more extensive development.

CLIMAX.—The new concentration plant of the American Metal Company, Summit County, for the handling of molybdenum, is rapidly nearing completion, and extensive development work is planned by the company. A satisfactory process of treatment has been perfected, and it is anticipated that a large tonnage of ore will be concentrated during the present year.

DENVER.—Fire recently destroyed a portion of the plant of the Chemical Products Company, Louisiana and South Jason Streets. The destroyed building was used exclusively for the production of vanadium for the British Government, and will be immediately rebuilt. The total loss is estimated at $50,000. Lafayette M. Hughes is president.

PUEBLO.—Plans have been completed and construction will be commenced at once on the new local plant of the Norcross Chemical Company, to be located near Stone City. The buildings include tank houses, acid towers, boiler rooms, and other structures, and will be used for the manufacture of acids, chemicals, and munitions. W. J. Cooper is construction superintendent.

Connecticut

NEW HAVEN. — The International Leather & Belting Company, Middletown Avenue, has had final plans prepared for the initial unit of its new plant, which will be one-story brick and steel, about 50 x 150 feet. The entire project is estimated to cost about $200,000. The company has recently acquired additional property in Middletown Avenue for extensions.

Delaware

WILMINGTON.—The E. I. duPont deNemours Company has recently commenced the construction of its proposed new shell-loading plant at Williamsburg, Va., to execute orders for the Government. The entire project is estimated to cost about $5,000,000.

WILMINGTON.—Fire recently destroyed the punch shop at the plant of the Pusey & Jones Shipbuilding Company, with loss estimated at about $75,000.

Illinois

CHICAGO.—The Chicago Bearing Metal Company, 2234 West Forty-third Street, is making rapid progress in the construction of a new one-story plant at 2216 West Forty-third Street. The structure will be about 100 x 225 feet, and is estimated to cost $15,000.

CHICAGO.—The Universal Concrete Products Company, 122 South Michigan Avenue, has commenced the construction of a new one-story plant, about 80 x 450 feet, on Port Washington Road.

CHICAGO.—The Railway Mine & Supply Company, 332 South Michigan Avenue, has commenced the construction of a new plant at Kincaid to consist of a one-story blacksmith shop, about 65 x 100 feet; one-story foundry, 60 x 375 feet, and one-story assembling works. The new plant will cost about $75,000.

SPRINGFIELD.—The United States Industrial Alcohol Company, New York, manufacturer of distilled spirits for industrial and medical purposes, and which operates a large plant in Peoria, has filed articles of incorporation with a capital of $18,000,000 to operate in Illinois. Of this capital $388,000 will be employed in the state.

Indiana

INDIANAPOLIS.—Fire, on January 23, completely destroyed the plant of the Stewart-Carey Glass Company, with loss estimated at about $150,000.

Iowa

DES MOINES.—Harry Cohen of the Cohen Brothers Iron & Metal Works, 307 East Third Street, and associates, are now organizing a large new corporation to have a capitalization of $1,000,000, for the erection of a large roller mill on the site of the old starch works, East Des Moines. It is said that the new plant will give employment to about 5000 hands when running to capacity.

Kansas

JOPLIN.—The Dick Turpin Concentrating Company, with concentrating plant situated on the Riseling land, just southwest of Joplin, has been acquired by the American Metal Company, and the concentrating plant will be removed to the recently acquired leases west of Baxter Springs. The Dick Turpin mill was erected by D. W. Sparks and associates about two years ago.

TOPEKA.—Fire recently destroyed a portion of the plant of the Pioneer Waste Paper Company, Ninth and Adams Streets, with loss estimated at about $10,000.

CHANUTE.—The City officials have awarded contracts for extensions and improvements in the municipal power plant to cost about $25,000. G. G. Wood is city clerk.

Kentucky

PADUCAH.—T. N. Hazelip and E. C. Phelps have leased extensive fluorspar properties in Crittenden County, Kentucky, and Hardin County, Illinois, and are planning for development of the mines.

Louisiana

SHREVEPORT.—The Marine Oil & Refining Company is said to be considering the immediate construction of a large new oil refinery. It is anticipated that the new plant will be ready for operation by the middle of the summer.

Maryland

BALTIMORE.—The United States Industrial Chemical Company has had plans prepared for the construction of a new one-story machine shop, about 80 x 100 feet, at its Curtis Bay works. The new addition will cost $50,000. The company is also planning for a new one-story copper shop to cost $50,000.

BALTIMORE.—The Poole Engineering & Machine Company has recently acquired additional property at its plant for extensions. Additions to the plant now under way are estimated to cost $500,000. The new plant now in course of construction will be used for manufacturing ordnance for the United States Government, and forgings for large guns will be the product of the foundries.

BALTIMORE.— The Bartlett-Hayward Company has acquired a tract of about 40 acres as a site for the construction of a large new plant for the manufacture of munitions. Contract for the new works has been awarded to Morrow Brothers, Fidelity Building, Baltimore.

EDGEWOOD.—The United States Government is having plans prepared for the construction of forty-eight buildings for a new shell-filling station for the Ordnance Department, the entire plant being estimated to cost $4,000,000. The works will include mixing warehouses, supply pumps, chemical and physiological laboratories, etc. The Mellon-Stuart Company, Pittsburgh, Pa., is the contractor

Massachusetts

ANDOVER.—Fire, on January 31, caused by an explosion, destroyed the plant of the Beaver Chemical Manufacturing Company, which was engaged on important work for the Government. The total loss is estimated at about $100,000.

SPRINGFIELD.—The Springfield Gas Light Company is planning for the installation of machinery for the recovery of toluol for Government use in producing trinitrotoluol for explosives. It is anticipated that approximately 30,000 gallons will be obtained annually. Charles H. Tenney is president.

WOBURN.—Fire, on January 30, destroyed a portion of the plant of the Merrimac Chemical Company, with loss estimated at about $10,000. It is said the damaged section will be immediately rebuilt.

Michigan

MARQUETTE.—Fire, on January 29, destroyed a portion of the plant of the Pioneer Iron Furnace Company, controlled by the Cleveland Bluffs Iron Company, of Cleveland, Ohio. The alcohol refining plant, primary building, and several condensers were completely destroyed, with loss estimated at approximately $150,000. This plant was one of the largest producing alcohol and other chemicals for the Government.

Minnesota

BRAINERD.—The Northwest Paper Company is said to be considering the construction of additions to its plant to double the present capacity.

Missouri

CARTHAGE.—Favorable progress is being made by the Pleasant Valley Mining Company, about three miles southwest of Carthage, on the construction of a new concentrating plant. The concentrate at this lease is particularly satisfactory, being lead free, less than 1 per cent in iron, and usually showing about 62 per cent metallic zinc.

KANSAS CITY.—The Winslow Manufacturing Company, manufacturer of tractors, has recently filed plans and awarded a contract for the construction of a new one-story plant, about 50 x 120 feet. The structure is estimated to cost $40,000.

WACO.—Fire recently destroyed a portion of the plant of the Putte-Kansas Mining Company, Jasper County, with loss estimated at $75,000. A section of the new 400-ton concentrating plant, recently completed, was also damaged. The mill will be immediately rebuilt.

Nevada

RENO.—The Consolidated Mayflower Mines Company has been making extensive developments for the production of milling and shipping ore on 200 and 300-foot levels at its Mayflower mine in Nye County, and 1400 feet northwest of the shaft a promising vein has been uncovered near the surface and opened to a depth of 35 feet The vein consists of excellent milling ore, with portions carrying a high gold content. The company will make extensive alterations and improvements at its mill. W. J. Tobin is president.

RAND.—The Nevada Rand Mining Company, located near Rand, is planning for the construction of a large new concentration mill.

New Jersey

MAYS LANDING.—The Bethlehem Steel Company is planning for the immediate construction of a large new local shell loading plant for the United States Government on its property along the Egg Harbor River, and it is anticipated that the new works will be ready for operation in about three months. About 2000 hands will be employed.

DOVER.—The International High Speed Steel Company, one of the comparatively new industries in this section, is now operating its works at full capacity for the manufacture of solid and hollow rock drill steel. The plant is located about two miles from the city, fronting on the tracks of the Lackawanna Railroad.

NEWARK.—The Balbach Smelting & Refining Company, 550 Market Street, has taken out a building permit for the construction of a new brick and steel addition to its plant, about 45 x 64 feet. The company will also make alterations and improvements in its casting and copper furnace works on Ferguson Street.

NEWARK. — The Butterworth-Judson Corporation, Avenue R, manufacturer of chemicals, will build a new one-story engine plant, about 57 x 110 feet, at its plant on Roanoke Avenue. The structure will cost about $25,000.

NEWARK. — The Northern Leather Works & Produce Company, 377 Broadway, New York, is having plans prepared for the construction of the first unit of its proposed new local plant on Backus Street. The structure will be three-story and basement, about 40 x 130 feet.

NEWARK.—The Heller & Merz Company, manufacturer of chemicals, dyes, etc., has filed authorization papers to operate in New York with a capital of $500,000. P. Schnerrenberger, 503 Hudson Street, New York, has been appointed representative.

PAULSBORO.—Construction has been completed on the new plant of the I. P. Thomas Phosphate Company, and it is planned to inaugurate operations at an early date. The structure was erected at a cost of $50,000.

ELIZABETH.—Fire recently damaged a portion of the plant of the Kalbfleisch Chemical Company at Third Avenue and Baltic Street. The destroyed section will be immediately rebuilt.

New York

NEW YORK.—The United States Industrial Alcohol Company, 27 William Street, has recently acquired the distillery of Clarke Brothers & Company, Peoria, Ill., and will make alterations and improvements for the manufacture of chemicals.

LONG ISLAND CITY.—The Central Smelting & Refining Company is having plans prepared for the construction of a new one and one-half-story plant, about 75 x 180 feet, at Borden Avenue, Hayward and Third Streets.

COLONIE.—The Colonie Fibre Company has awarded a contract to Lewis & Bennett, Troy, for alterations and improvements at the plant formerly occupied by Crampton & Beldon. As soon as this work is completed machinery will be installed for the manufacture of woolen fibre.

SYRACUSE.—Fire, on January 27, destroyed a portion of the plant of the Syracuse Rendering Company with loss estimated at $100,000.

MECHANICSVILLE.—The United States Government is planning for the immediate construction of a large new chemical plant to utilize the by-products of the paper manufacturing plants of the West Virginia Pulp & Paper Company. The works will specialize in the production of acetone, which is used to mix with varnish for coating aeroplane wings.

Ohio

CANTON.—Fire recently destroyed the plant of the Miller Pasteurizing Machinery Company, manufacturer of pasteurizing and other dairy equipment, with loss estimated at $200,000.

CARTHAGE.—Three of the five main units of the Hess Spring & Axle Company plant, 124 West Sixty-sixth Street, were destroyed by fire on January 23, with loss estimated at about $100,000.

LEETONIA.—The Fabricated Steel Products Company recently organized with a capital of $150,000, has acquired the plant of the Leetonia Boiler Company, and is planning for the installation of new equipment, including punches, spitting shears and riveters, to provide for increased capacity. The company is engaged in the manufacture of boilers, tanks, wireless towers, and other plate material work for the Government.

LIMA.—Fire on January 29 destroyed a portion of the plant of the Townsend Oil Products Company, with loss estimated at $20,000.

LORAIN.—The J. C. Cromwell Steel Company, manufacturer of steel billets and other steel products, is planning for the construction of five new blast furnaces at its plant to provide for increased capacity

TOLEDO.—The Buckeye Paint & Varnish Company, manufacturer of paints, varnishes, etc., is planning for the early construction of a large new three-story addition to its plant, to provide for increased capacity

Oklahoma

ARDMORE.—The Chickasha Refining Company is making rapid progress in the construction of a large new refinery to have a daily capacity of about 3000 barrels, and it is anticipated to inaugurate operations at an early date.

MIAMI.—The Ken-Tex Company, recently incorporated with a capital of $200,000 to mine for lead and zinc, is planning for the construction of a large new mill.

OKLAHOMA CITY.—The Medical Mining Company, recently incorporated with a capital of $200,000, is planning for the immediate development of about 40 acres of lead and zinc lands and the erection of a 250-ton mill.

Oregon

GOLD HILL.—O. C. Runnalls, Seattle, Wash., and associates, who recently acquired the Utah and Bertleson groups of cinnabar mines, twelve miles north of Gold Hill, are planning to equip the properties with a mercury-reduction plant of 100 to 200 tons capacity.

TAKILMA.—The Atlantic Ore & Alloys Company, Philadelphia, Pa., is planning for the construction of a new plant at the Golconda chrome mine, to have a capacity of about 100 tons daily. Development at these properties has been suspended for the past few months. R. J. Rowan is manager.

Pennsylvania

ALLENTOWN.—Fire, on January 16, damaged the No. 7 tempering plant of the Saucon mill of the Bethlehem Steel Company, used for the manufacture of gun forgings, with loss estimated at $10,000. It is said the destroyed section will be immediately rebuilt.

PHILADELPHIA. — The Philadelphia Paper Manufacturing Company is planning for extensive alterations and improvements at its plant to provide for increased capacity. The work is estimated to cost $25,000.

PHILADELPHIA. — Fire recently destroyed a portion of the glass manufacturing plant of H. Perlstein, 510-18 South Randolph Street, with loss estimated at $50,000.

PITTSBURGH.—The Carbon Steel Company has taken out a building permit for the construction of a large new coal gas producing plant on Putney Way, between Thirty-second and Thirty-third Streets. The new works will be of steel and concrete construction, about 35x185 feet, and are estimated to cost $225,000.

PITTSBURGH.—The Eagle Paint & Varnish Company, 225 Galveston Avenue, manufacturer of paints, varnishes, etc., has recently completed alterations and improvements at its plant to provide for increased capacity.

TYRONE.—The United States Government is planning for the construction of a large new plant on local property owned by the West Virginia Pulp & Paper Company, to be devoted to the manufacture of alcohol and other chemicals from the liquor in which wood is prepared. The new plant will give employment to about 250 hands. The works will be taken over and operated by the West Virginia company as soon as the Government desires.

WILLIAMSPORT.—Fire recently destroyed a portion of the plant of the National Foundry & Manufacturing Company, which was engaged on some important work for the Government. The loss is estimated at about $40,000, including the destruction of some valuable patterns. The destroyed section will be immediately rebuilt.

Rhode Island

PROVIDENCE.—Fire recently destroyed a section of the plant of the Providence Dye Works, South Angell and East River Streets, manufacturers of dye-stuffs, with loss estimated at about $35,000.

Tennessee

CHATTANOOGA.—The Tennessee Bauxite Company, recently organized, has acquired the lease of a large deposit of bauxite which has recently been operated up near Hixon, and is planning for immediate development. The mine is located about fifteen miles northeast of Chattanooga, near the Tennessee River.

COLLINWOOD.—The Tennessee Iron & Railroad Company is planning for the construction of a large new plant to be devoted to the manufacture of wood alcohol, acetic acid and acetone, with charcoal as a by-product. The plant will be owned by the Government, which will utilize all the product with the exception of the charcoal, which the Tennessee corporation will use for fuel in its iron furnace now under construction. The project will cost about $800,000.

KINGSPORT.—The Kingsport Wood Reduction Company, recently incorporated by Chicago capitalists, is planning for the construction of a large local plant for the manufacture of wood distillates. Estimated cost of the work is $700,000.

MT. PLEASANT.—The International Agricultural Corporation is planning for the immediate reconstruction of its phosphate plant recently destroyed at a loss of about $15,000.

Texas

RUSK.—T. L. Featherstone & Company, who recently acquired the furnace and pipe foundry from the State penitentiary, are making extensive alterations and improvements, and are planning to inaugurate operations early in the spring, the furnace to have a capacity of about 100 tons of pig iron daily, and the pipe foundry, about 50 tons of water pipe daily.

West Virginia

MORGANTOWN.—The Star Glass Company, near Star City, is planning for the immediate reconstruction of its plant recently destroyed by fire with loss estimated at $100,000.

Washington

HOQUIAM. — R. Thomas, manufacturer of paper and pulp, has made announcement that plans are under consideration for the construction of a large new local plant for the manufacture of wood pulp and paper, to have an initial capacity of about 100 tons of pulp daily.

SPOKANE.—The Coeur d'Alene Antimony Mining Company, is planning for the establishment of a large electrolytic antimony plant for the handling of ore taken from the company's properties on Pine Creek, Idaho. H. E. Jolly is president.

Wisconsin

MILWAUKEE.—The Hummel & Downing Company, Thomas Street and North Cambridge Avenue, manufacturer of box-board and fibre-board, has completed the construction of its new 140-inch paper mill, and operations have been inaugurated. The new plant was erected at a cost of about $800,000.

RACINE.—Fire recently destroyed the main building of the Belle City Malleable Iron Company, with loss estimated at about $75,000.

Wyoming

RIVERTON.—The Riverton-Wyoming Refining Company is planning for the construction of a large new oil refinery to cost about $127,000. Plans for the plant, which will have a capacity of 3,000 barrels, are being prepared.

Alaska

TREADWELL.—The Alaska Treadwell Company is planning for the immediate installation of new equipment at the Treadwell molybdenite mines at Shakan for early development work. It is said a new concentrating plant will also be erected.

Canada

SUDBURY.—The British American Nickel Corporation is making rapid progress in the construction of a new electrically-operated smelting refinery, which will have a capacity of 2,500 tons of ore daily and a nickel production of 20,000,000 pounds per annum.

PORT COLBORNE, ONTARIO.—The International Nickel Company has commenced the erection of a large new refinery which is estimated to cost $4,000,000, to have an initial capacity of 15,000,000 pounds per year. It is anticipated to inaugurate operations within the next few months.

Trade Notes

HESS & SON, Philadelphia, Pa., manufacturers of Tinol paste solder, wire solder, alcohol torches, and flux, and epicassit, have removed to 1302-4 Filbert Street, where increased manufacturing facilities are available.

THE DRIVER-HARRIS COMPANY, Harrison, N. J., announces that it is now prepared to supply 99 per cent cold-rolled pure nickel sheets. On Jan. 1, there was distributed to all employees having been with the company at least six months on that date a life insurance policy to an amount of $500. It is the intention of the company to make further distribution of these policies as other employees reach the six months service period. The fourth annual dinner of the company was held at the Down Town Club, Newark, on Friday evening, Dec. 28, and was a very enjoyable affair. The entire office staff and the heads of the factory departments, and veteran employees of the company were invited. The number participating was approximately 146 persons. After dinner was served and some short speeches were heard, the evening was devoted to dancing and recreation.

DYESTUFFS IN THE TRADE OF SIAM.—Aniline dyes are not manufactured in Siam, according to a consular report, and the native vegetable dyes with which the Siamese in the past produced the enduring, bright, and beautiful tints on their homemade garments are now being displaced largely by imported dye-stuffs. Dyeing in black, however, is still an important industry in Bangkok. Considerable quantities of silk piece goods are sent from China each year to be dyed in the juice of the green berries and leaves of the native tree "maklua" (*Diospyros mollis*). This imparts to the fabric a bright jet-black color which will stand washing. Stuffs dyed in this preparation are enhanced in value. Siam's imports of dyes of all sorts for the years ended March 31, 1914, 1915, 1916, and 1917 were: For fiscal year 1914, 563,090 pounds valued at $70,936; for 1915, 459,033 pounds valued at $49,590; for 1916, 736,876 pounds valued at $50,166; and for 1917, 974,845 pounds valued at $87,360. The imports for the fiscal year 1917 consisted of 102,418 pounds of aniline colors valued at $34,126; 805,252 pounds of indigo valued at $40,197; and 67,185 pounds of all other dyes valued at $13,037. Of the aniline imports for last year 88,102 pounds were shipped from Holland, and 11,636 pounds from the United Kingdom. Nearly all shipments during 1916-17 were made from oriental ports. There were no exports of dyes from the United States to Siam during that period.

THE PRATT ENGINEERING & MACHINE CO. of Atlanta, Ga., has changed its New York office from 61 Broadway to 25 West Forty-fourth Street.

Manufacturers' Catalogs

THE TITANIUM BRONZE CO., INC., 504 Marine Bank Bldg., Buffalo, N. Y., has issued a booklet describing its method of manufacturing phosphor bronze castings.

BACHARACH INDUSTRIAL INSTRUMENT CO., Pittsburgh, Pa., has issued a pamphlet describing "hydro" gas meters.

LINK BELT CO., Chicago, Ill., has issued a booklet entitled "The Ideal Drive for Rubber Mill Machinery."

KAESTNER & HECHT CO., Chicago, Ill., have issued an attractive catalog describing their line of paint machinery, including mixers, mills, tanks and special apparatus.

RUBBER INSULATED METALS CORPORATION, Plainfield, N. J., has issued a pamphlet describing "Rimco" rubber insulated pliers.

PYROLECTRIC INTRUMENT CO., Trenton, N. J., has issued circular No. 9, describing the Northrup millivolter for accurate e.m.f. measurements up to one volt.

Discipline

OCCASIONALLY an American has been both bold and frank enough to remind us that as a nation we have a distaste for discipline and a lack of respect for authority; but our complacency has shed the criticism as effectually as a duck's back turns water. Having given no heed to our own critics, perhaps we will the more gracefully accept the same sentiment when expressed by a friendly but earnest ally.

It would have had a salutary effect if every intelligent man in this nation could have been sobered by the direct challenge of Capt. Hodder-Williams, of the British Expeditionary Force, when he told the mining engineers assembled in New York that America's greatest need was discipline and that without it we could not hope to win the war. He spoke as one who has been tried by fire and who knows what it is to lead troops in whose discipline there could be no question. He stated the problem tersely when he explained that discipline must extend beyond the army throughout the whole people, and he illustrated this need clearly when he said that the allied armies would take care of the German military forces, but that the American people must match the German people in discipline—discipline in saving, discipline in co-operation, discipline in sacrifice, discipline in service and discipline in loyalty to the government. The German people are disciplined, and that quality has told in their favor. We too must achieve that end, self-taught because no stern, harsh and rigorous government has trained us. We may scorn the outward and visible signs of discipline, but we must learn to value the inward grace. The great task set for the American people by our ally is self-discipline.

A Little Homily on the Tariff

AT A MEETING of the editors of technical journals held in Washington some time ago, Chairman Taussig of the United States Tariff Commission impressed urgently upon those present the fact that the commission was the creature of Congress and that its function was to present facts. "Our business," said he, "is to gather information, and submit reports to Congress to enable the Congressional Committee and the legislative bodies to deal knowingly with the problems that are presented to them." He said many other things, some of which were confidential and others for publication, and his exposition was at once able and thoughtful. But let us content ourselves with the foregoing as a text, and consider some features that relate to it, most of which he did not mention.

When a tariff bill reaches Congress it has a hard row to hoe because the agents of special interests are always present, and they move to amend in such a way as to benefit the constituent or friend of the amending

representative. It is likely that the information available from the commission will aid in preventing jokers and trades between Congressmen because the proper co-ordination of facts leads to the truth, and when the truth is made intelligible in this manner tinkering becomes difficult.

We know very well that Congress can, by a single enactment, ruin a large part of American industry. There is no reason to think that it will, unless bolshevikitis becomes epidemic in this country, and in that event it will not make much difference what the laws are. But even with our faces turned toward the morning and with hope alive within us, there is one thing of which we may be sure; and Congress is bound to be very sensitive about it because the people at large are growing increasingly so. It will not do any more to "put something over" upon Congress. The general welfare must be considered and not that of special interests. If a heavy duty on some article made here under difficulties is likely to cripple industry at large, it becomes the obligation of the industries that use the product to look out for this link in their chain of needed materials to the end that they can get it made here at a reasonable price. If Congress is asked to make it duty-free, very likely it will—and then it will proceed to make other things duty-free. Congress does not always discriminate with nice precision. If a high duty is imposed, then industry at large will want higher duties to meet the increased cost, and that is the road of danger that leads along the line of soap boxes from which orators call for unconditional free trade and free love and free property.

The Tariff Commission can give no aid in this connection.

Another feature of leading importance that calls for an entirely new angle of vision from manufacturers is the relation of tariff duties to wages. The old line of argument was to generalize and to claim maximum duties for the benefit of the American workingman, no matter whether he got the benefit in whole or in part or not at all. The Commission, on the other hand, will look for the specific relations of labor to product; and generalizations fall down in the face of co-ordinated facts unless they support them. It will examine the relation of import duties to wages in detail; it will exhibit facts instead of claims. Heretofore the welfare of labor has occasionally been used as an argument to cover paucity of research on the part of American manufacturers. That will not do any more. American products must take their places beside those of foreign make and stand or fall by the comparison. Shiftless factory practice and wasteful processes will display themselves without mercy. Scientific research in foreign laboratories must be met by research in American laboratories and these results must be applied to factory practice. This war is causing the whole world to grow very much in earnest. It will not do to regard the tariff, as it frequently has been regarded in the past, as a substitute for research. Progressive industry cannot endure such a wrench in its intermediates any more.

In short, with the world sick with grief over death, and weary with the fever of anger and war, it will not do even to think that prosperity may be achieved by legislation alone. Everybody must work, not only hard but with intelligence. There will be no protection for the incompetent.

The Chemical Alliance

IT was necessary to disband the advisory committees of the Council of National Defense because of a law which was passed making it a misdemeanor for anyone acting in an official advisory capacity to the government to counsel the purchase of wares produced by an organization in which he is interested. Inasmuch as the committees comprised the leading manufacturers of the country no other course was open. At the same time a great deal of useful work had been started, and it was suggested that to meet the needs of the government each industry proceed to organize itself. The Chemical Alliance was proposed for the chemical industry as a whole and this received the hearty approval and encouragement of the War Industries Board, more particularly Mr. Baruch, who, as Commissioner of Raw Materials, has to do with the purchase of chemicals.

There was a considerable number of organizations already established, and without taking the place of these—none of which covered so wide a field—the Alliance sought to profit by their facilities as much as possible. Two noteworthy organizations were those of the fertilizer manufacturers which has active headquarters in Washington, of which Mr. Horace Bowker is the head, and the Manufacturing Chemists' Association, of which Mr. Henry Howard is chairman of the executive committee. At the first annual meeting which we reported in our last number, these gentlemen were elected respectively president and vice-president of the Alliance, and a board of directors consisting of men who occupy the first rank in chemical industry was chosen.

The Alliance has a great deal to do, as we shall observe in the enumeration of some of its problems.

There is co-operation with the government through the Army, Navy and War Industries Board in the continuation of statistical work. An important feature in this connection is the revision of the forms sent to manufacturers for the purpose of gathering information. The forms as prepared have overshot their mark in calling for such elaborate detail that large and important corporations cannot furnish it within reasonable time or without serious disturbances to their procedure.

Co-operation with other boards in the matter of foreign pyrites is needed so that the proper distribution of the material when it is received to the points where it is most urgently required at the time, may be provided for.

The question of supply against the increased programs of the War Department is important. If it is resolved to increase the production of certain munitions, the availability of the necessary materials is immediately studied and the most expeditious and economical program is worked out and presented. In this connection the opinions of the leading men in the trade are of distinct value.

The question has occasionally to be determined as to certain materials, whether they are made here or not; if they are made, who makes them; and if not, who is equipped to make them.

Statements from all the members of the Alliance as to what they can produce constitute information that is far more enlightening than statements of two

or three makers in response to inquiries sent out in the usual manner. This detailed information as to the capacity of an industry, right up to the minute, with the chances of profiteering reduced to the minimum, is something that never has been available before in this country. It also solves problems relating to coal and transportation, showing how the government may supply its needs with the least freight movement. Shipments, for instance, of the same material from one producer in New England to the Middle West and from another producer in the Middle West to New England may thus be avoided in government work at a great saving of time and haulage.

The very delicate question in the case of shortage of supplies as to which industries may be curtailed with least injury to the general welfare is one to be carefully studied and the results contributed to the government authorities if they are asked for.

As chairman of the former Advisory Committee, Dr. Nichols introduced a very profitable method of procedure whereby, at each meeting, the chairman of each section told what had happened within his section since they had last foregathered. This enabled the committee to make studies of products that were bound to be called for, but for which the authorities had not yet formulated their requests. The method has been continued.

In other words, here is a great organization, built up of the leading men in chemical industry, the purpose of which is to help win the war. All manufacturers of chemicals are urgently invited to join it. It is neither a kicking committee nor a profiteering layout. It is the strongest and ablest manufacturing board ever brought together in the United States in chemical industry.

Manufacturers should swallow their fears that competitors may find out something about them and join. We have just one arch-competitor now and that is the German Army and Navy, coupled with the German High Council of Deceit. The only way to beat it is to pull together.

Competition in Steel After the War

LONDON *Engineering* has a very interesting editorial, printed in part elsewhere, as to the prospect of iron and steel competition between Britain and the United States after the war. There is a decidedly able review of what has occurred in the past 30 years, Britain losing her supremacy, Germany coming to the front and the United States failing to make good the promise of 15 or 20 years ago as to its place in the international market, but the editor is less precise when referring to prospects after the war. He inclines to the general belief that costs will be high in the United States, and as to Britain, he is rather oracular—Delphic oracular—in saying that it "rests with themselves," that their statesmen must protect their markets and encourage enterprise; that manufacturers and shippers must organize better and the workmen must adopt a more enlightened attitude.

Without wishing to steal any one's ideas, we venture to observe that the same remarks made about the United States would not be altogether lacking in point. If our government will co-operate with business—and the ice has certainly not merely been broken but melted in the past twelvemonth—not if our manufacturers and shippers will organize better, but if the government will let them, and if our workmen take a reasonable view as to working hard and a decent number of hours, we can do a great deal.

In detail, however, we think somewhat more specific speculations can be indulged in as to American industry immediately after the war, say for a couple of years, than are hazarded by our London contemporary. In the first place, there will be a shortage of shipping. "Ships will win the war," and it seems obvious, therefore, that the war will be won long before there are enough ships for the regular commerce of the world. Demobilization will employ a great many ships, moreover. Export trade will be confined largely to the more valuable and more highly finished products, including machinery, for instance, rather than the tonnage products of the iron and steel industry.

Apart from ocean shipping conditions, the position of the United States in relation to the rest of the world will be altogether altered. Before the war it was necessary to have a large favorable balance in merchandise trade in order to meet various requirements, including payments on American securities held abroad. We quote from the annual report of the Comptroller of the Currency, made Feb. 1, to the effect that since the war started the favorable merchandise trade balance has resulted in our importing about a billion dollars of gold, in practically paying off five billions owned abroad in the shape of American securities, and in our loaning foreign countries two billions, apart from the large advances made by the government itself to our Allies. In such circumstances, merely to "break even" as we did in the past would involve our importing much more merchandise than we exported, instead of the reverse as was formerly the case.

The circumstances will be such as to require the keenest effort to maintain a large export trade. Prices will be high in the United States, the essence of the situation being that the gold dollar will be cheap. That will tend to make it difficult for us to export, but easy for us to conduct a large domestic trade. A very large consumption of iron and steel will naturally be involved. It is natural that our friends abroad should wonder what we are going to do with our surplus when we increase productive capacity as we have done in the past two years. We have pondered the same idea ourselves. In previous cases of expansion, however, we found employment for the surplus at home after all. Our foreign trade did not grow in the past in keeping with our expanding production.

In the matter of international competition we have, perhaps, even greater obstacles to overcome than our London contemporary considers. The period was very brief when we made particularly cheap steel. It was when we were using Mesabi ore from just beneath the surface, with a ridiculously low cost of mining, and ore that was very much richer than what we are forced now to use. More ore must be transported per ton of pig iron, and much more limestone and coke used. Measured in absolute units of effort expended and equipment used, not in the fluctuating standard of the gold dollar, our cost of producing steel is much higher than when we made our reputation in the closing years of the nineteenth century.

Factors in World Trade Competition

A CRITICAL analysis of world trade in iron and steel recently appeared in the editorial columns of *Engineering* (London), from which we make the following excerpt:

The future race for supremacy in the iron, steel and engineering export trade, the world's most important group of manufacturing industries, will probably be mainly between the United States and the United Kingdom. In the last thirty years before the war the Germans increased their output of iron, steel and engineering products, measured in terms of pig-iron, from 3,000,000 tons a year to 19,000,000 tons. In the same period we only increased our output from 8,000,000 tons a year to 9,000,000 tons. In the last fifteen years before the war the protected, organized and subsidized German trade increased its exports of iron and steel goods from less than 1,000,000 tons a year to 6,000,000 tons, while we in those fifteen years only increased our exports of iron and steel from 3,500,000 tons a year to 5,000,000 tons. We lost the lead because we failed to protect our industries, failed to organize, and failed to work hard. Our statesmen would not give productive industry the slightest protection or encouragement, or even the commonest of fair play. Our manufacturers and shippers would not drop their conservatism, or sink their individualism and co-operate for the common good. Our workmen lost 100,000,000 separate working days by strikes in ten years; they opposed machinery; they limited apprentices, and deliberately "slow-timed" their work. After the war we have to protect and organize and develop our industries on common-sense lines, work diligently, enter into preferential trading arrangements with our Colonies and Allies, and avoid German goods. We have to wake up and do these things or perish. We can easily beat Germany if we try * * * but there remains the question of American competition.

It is, therefore, useful to examine broadly the comparative resources of the United States and the United Kingdom. Roughly, there was a world's export trade in iron and steel aggregating 18,000,000 tons a year before the war, valued at more than £200,000,000, besides machinery valued at another £20,000,000. In round figures, Germany was exporting 6,000,000 tons of iron and steel annually; Britain, 5,000,000 tons, and America, 1,500,000 tons. After the war it is more than probable that this trade will be greater in volume and much greater in value than before the war. It is highly likely that Germany's share will be much smaller than it was before the war, which means that more will stand to be divided between the United Kingdom and the United States. By the way, these three countries—America, Germany and Britain—produce somewhere about 85 per cent of the world's total of iron, steel and engineering products. Until the outbreak of war the United States, although possessing a productive capacity equal to that of Britain and Germany put together, never had more than a meager share of the world's export business, as indicated by the above figures. But the opinion is strongly held in some quarters that America will henceforth undertake an export trade in some way commensurate with her capacity of production. What are the prospects? Briefly, it may be said that in abundance of natural resources and in amplitude of productive capacity, the United States is in a position to undertake something like the lion's share of the steel export business, easily beating both us and the Germans; but that in geographical compactness, in the powers of cheap production, and in shipping facilities Britain is much better situated. The United States has the most coal and iron ore. The United Kingdom has the best assemblage, manufacturing and shipment accommodation.

In order to weigh up the position and prospects it is necessary to take a glance backwards. Between fifteen and twenty years ago, while the resources of America—and of most other countries, for that matter—were egregiously exaggerated, not only by American, but by our own public speakers and writers, our own resources were just as absurdly underestimated. It was boldly declared that America could produce the cheapest steel; that we were rapidly becoming industrially bankrupt through the exhaustion of our coal and iron supplies, and the United States would soon flood the world's markets with manufactured goods at prices we could not touch. But the threatened "American Invasion" did not materialize. The Americans vastly increased their capacity. Between 1900 and the outbreak of war they increased their steel works capacity, in terms of pig-iron or steel ingots, from 15,000,000 tons a year to nearly 40,000,000 tons. But they exported very little more in 1914 than they did in 1900. The bulk of the world's export business had gone to the Germans. Relatively, the Americans declined from a promising second to a bad third place in the race, whilst the Germans went rapidly ahead from third to first place, and we fell from a long lead to the second position. If we had paid less attention to the threats of American competition, to the exaggerations of the resources of other countries, and to the scares about our own supplies of raw materials, and had kept our industries advancing concurrently with the world's growing demand for manufactures, we should never have been beaten by Germany, nor need we have feared the competition of any other country. Although our combined productive capacity was less than that of the United States, we exported something like 10,000,000 tons of iron and steel a year, against America's 1,000,000 tons to 1,500,000 tons.

Now, in view of the coming new international competition, it is of prime importance to inquire why the United States, with such a huge capacity of production, has taken such a meager share of exportation business. The reason is that our American rivals have been unable to produce and ship steel goods at competitive prices, notwithstanding all their great natural resources. And this brings us to the central and supreme fact in the issues involved. With their iron ore deposited a thousand miles from their coal mines, and their iron and steel works mostly between 400 miles and 500 miles from the seaboard, and with wages and salaries exceedingly high, the Americans have not been able to sell at a profit, or at competitive prices, outside their own protected home market. Just as the Americans rapidly increased their works capacity, so the costs of their manufacture advanced.

From time to time we hear a great deal about the superiority of American labor, but the figures given in this connection are misleading. They make no due allowance for the vastly greater expenditure on machin-

ery and automatic appliances in America, compared with Britain. If half what we have been told so often about American efficiency and economy had been true, British goods would have been swept clean off the world's markets long ago. The simple fact is that the Americans cannot produce and ship general manufactured goods so cheaply as we can. Some high authorities hold the view that one economic effect of the war will be so to enhance our costs as to enable the United States to produce and ship at least as cheaply as ourselves and the Germans. Many American enterprises and associations are laying their plans in this belief. Much, if not everything, will depend upon ourselves. If we stick too closely to old methods and policies we may be beaten both by American and Germans, not to mention other nations. If our statesmen will not protect our markets and encourage enterprise more than they did before the war, if our manufacturers and shippers will not organize better, and if our workmen will not adopt a more enlightened attitude toward machinery and large-scale production, we shall certainly be beaten. But with anything like intelligent co-operation between the state and industry, and between capital and labor, we should again obtain and retain supremacy in the world's export trade. While the Americans should enjoy highly prosperous trade in their own rich, protected home market, and obtain a considerable share of international business hitherto done by the Germans, we should easily take a long lead in the trade in manufactured exports, and also in shipping.

The Administration Water-Power Bill

IT WILL be interesting to relate some of the facilities that are available for water-power development, the reasons why they are not developed, and to point out what is necessary to bring this about.

The occasional River and Harbor Bills that have been brought before Congress have been justly criticized. They provide in part for prospective river transportation with but rare provision for the use of the power available at or near the dams. Vast sums have been appropriated and some work has been done here and there in the hope that tug boats and wooden or steel barges would come along and carry things—but in the main they haven't come along.

The waterways and power sites of the country are under three departments of government. The navigable rivers, including those that are prospectively navigable —that is, extensions that may be made by dredging, digging canals and the construction of locks and dams —are under the jurisdiction of the Secretary of War. This jurisdiction is changeable and may be extended or withdrawn according to his judgment. The waterways which extend through public lands are under the jurisdiction of the Secretary of the Interior. Those in the national forests are in the keeping of the Secretary of Agriculture. This divided authority has discouraged progress.

To get at the matter more concretely, consider the situation in regard to some thirty-two rivers now held to be either navigable or prospectively so, which are under the jurisdiction of the Secretary of War. The list does not include the Hudson or any stream which has reached its possible development. On these thirty-two rivers alone there is 10,183,950 hp. available. The development of this would add the possibility of 4324 miles of navigable waterways, in most cases where they are greatly needed. In providing for water-power developments by private capital it is right and proper that the interest of navigation be made a part of the contract. The cost to the government for building the necessary canals is then but a fraction of what it would be under the old River and Harbor Bill method, because dams and slack water are already provided by the water-power enterprises.

Another advantage to transportation that would accrue is that reinforced concrete barges may be built very cheaply within a short time and the means of propulsion of such barges is often available at the waterpower sites. When we burn coal to make steam to push a boat ahead a vast amount of energy is lost in pushing the water back. With proper electric towing facilities this energy is not lost, and the question of transportation of heavy staples in the open season by rail drops out of consideration except where the traffic is too light to bear the cost of installation.

Abundant and cheap water transportation thus becomes available as soon as our water powers are developed. Log-rolling and inertia are likely to disappear as soon as a proposal of this sort becomes concrete and the public knows what is to be expected of it. Then the completion of the whole will be demanded instead of the wasteful expenditure of money for the major purpose of bringing it into circulation in local districts.

Now of these water-power resources of 10,183,950 hp.—and they are nearly all attractive engineering possibilities—there are already developed, so far as we are able to gather, 611,141 hp. Over 9,500,000 available horsepower on these thirty-two rivers is undeveloped. The mileage of canals already built is insignificant.

Why is this? First, let us remember that it takes far more effort to build a great machine and to start it than it does to stop it and break it down. A monkey wrench or some emery powder or any one of a great many insignificant things can stop a machine. It is the same with the machinery of capital in great undertakings. Capital invested in water-power propositions is a long time investment. It does not turn itself over every year or even oftener than once in eight years. It is necessary that the fee or title to such property be good because the sums required are very large and the investor cannot get in and get out like a trader on the Stock Exchange. Titles to water-power developments have always been rather complex in this country. The United States Government is sovereign, and licenses can be recalled, although it was held that they would not be. With this in view, from ten to fifteen years ago the prospects for the construction of water-power installations were very favorable, and many projects were under way. But on February 27, 1909, the Hon. James R. Garfield, 2nd, then Secretary of the Interior, withdrew the permits to twenty-five water-power grants on the ground that it was desirable to bring all licenses under new and more restricted rules. The effect upon further developments was disastrous, not because of new restrictions, but because, after all, the government might and in fact did withdraw licenses after they had been granted. That is

what threw the scare into capital. We are not condemning Mr. Garfield; he did what he thought was right, without doubt; but he certainly gave a jolt to the growth of water-power developments.

Another cause may be found in the fashion and style of the thought of the day. It has been and still is held to be contrary to public policy to allow anyone or any corporation which enjoys a special permit or license from the government to grow very rich. We shall make no comment upon this fashion; it is in vogue and we should be only wasting our substance in opposing it, while it does not need our aid in its growth.

Our present laws controlling the development of navigable streams give tenure for a maximum of 50 years, but at the end of that time the United States Government may not only take over the property without compensation, but even charge the licensee with the cost of dynamite to blow up his dam. The result of all these causes is hardly less than an embargo on the industry.

In the last Congress the Shields Bill in the Senate provided a plain contract for 50 years on "navigable" streams (the term being used in the sense of the War Department as indicating also those prospectively navigable). At the end of such time the government was to have the option to take over the works at a fair value, or, if this was not done, the original grantee was to remain in possession for an indeterminate time subject to the pleasure of the government. It provided for the regulation of rates of service and maintained that navigation was of paramount interest. It provided also among other things that if Congress should cancel the grant the owner should be indemnified for his investment at a fair value.

This met with violent opposition from Mr. Gifford Pinchot and his followers; one of the principal objections being that the grants would be, in effect, perpetual investments, as the inertia of government would be too great to provide for taking over the property after 50 years. It was also held that the government should not pay for appreciation in value.

This year an administration bill has been introduced which is full of merit. It provides a commission of the Secretaries of War, Interior and Agriculture, who shall be in a position to give a license for 50 years. At least two years before the expiration of the term the licensee may apply for a new grant. This the government may allow or it may take over the property at a fair value not to exceed the actual cost, or a new license may be granted to a third party who shall pay to the original licensee a fair value not to exceed actual cost or, again, a new license may be granted to the original licensee under the terms of the then existing laws. The Commission may impose a rental for such sum as it may determine, but at a minimum of 10 cents per horsepower-year.

The measure as a whole, which includes supervision of rates and service, is an excellent one with the exception of certain features which may be eliminated; or they may have to be included by way of compromise. The 10 cents per horsepower-year is a light tax, but it has the effect of discouraging the development of reserve power before it can be sold. If the incidence of this or even a higher tax were to apply as soon as power is sold rather than as soon as it is developed, it would appear to be better.

The main thing is to get the bill passed. It provides a 50-year contract, irrevocable except for just causes, and with some small changes in minor particulars will make of water-power developments a fair banking proposition. Control of rates and service is now an accepted factor in public service corporations and the hazard of confiscation by burdensome impositions is no greater than with others. A secure title is absolutely necessary and this seems assured for 50 years.

It would seem reasonable to hold, with rates and service under supervision and with publicity in financing and accounting provided for, that security of possession and the avoidance of actual loss of investment under recapture at the end of the license, would provide for the lowest cost of organization and consequently the lowest cost of service, and that low cost of service would be reflected in rates. United States bonds sell because they are safe; if there were a question of discount at redemption, the discount would show in the price. The injection of hazards into a security puts it over into the speculative class, depreciates its value at the start, and makes it a rich man's opportunity. If the security is good the bonds are easy to sell, bonuses do not have to be given, the poor man can invest his savings in it and nobody is likely to get surprisingly rich out of it. If the site is good or the power is needed, the investors after all may make good money out of it, and that is, according to a certain prevalent school of political philosophy, a thing to be avoided at any cost whatever.

The passage of this bill, or one with equally fair provisions, is urgently needed. We urge it with all our might in the name of electrochemistry, which bids fair to leave this country if additional water power is not soon at hand. We urge it for American farmers who need cheap water transportation, as do the manufacturers and merchants of the interior. And we urge it for the general welfare.

New Western Office of Metallurgical and Chemical Engineering

FOR the past eight years METALLURGICAL AND CHEMICAL ENGINEERING has maintained a Western editorial office at Denver to enable it to reflect accurately the progress of Western metallurgy. Recently that office has been established at 1101 Newhouse Bldg., Salt Lake City, Utah, in charge of Mr. Ernest E. Thum, a metallurgical engineer trained and experienced in Western practice. Centrally situated in the region west of the Rocky Mountains, Salt Lake City has gained increasing importance as a metallurgical center, and the establishment of our office there will enable us to keep in close touch with developments. Our readers are invited to call upon Mr. Thum for any service he can render.

Coming Meetings and Events

Dyestuff Association of America, Rumford Hall, Chemists' Club, New York, March 6.

American Electrochemical Society, Spring meeting, Southern trip, week of April 28.

American Society of Mechanical Engineers, Worcester, Mass., June 4-7.

American Society for Testing Materials, Atlantic City, June 25-28.

New York Meeting of the American Institute of Mining Engineers

Notable War-Time Gathering of Mining Engineers in Annual Session. Report of Business and Technical Sessions. Sidney J. Jennings Elected President. Fall Meeting to Be Held in Colorado

THE 116th meeting of the American Institute of Mining Engineers, held in New York, Feb. 18 to 21, was a notable gathering of engineers in war time. In many respects the programs had a war interest and value, and the spirit of national service was much in evidence. All things considered, there was a generous attendance from such distant states as Montana, Colorado and Missouri, particularly the last where the preceding meeting was held.

Annual Business Meeting

The tellers appointed to canvass the ballots for officers for the year, beginning March 1, declared the following results: President, SIDNEY J. JENNINGS; Vice-Presidents, HENRY S. DRINKER and ROBERT M. RAYMOND; Directors, F. G. COTTRELL, HENNEN JENNINGS, GEORGE C. STONE, SAMUEL A. TAYLOR and ARTHUR THACHER.

The amendment relating to qualifications for membership in the Institute was carried by a vote of 1123 to 59. Under the terms of the amendment, which has been published in the Institute *Bulletin*, future members will have to meet certain requirements and will be classed accordingly.

Plans were made to hold the fall meeting of the Institute in Colorado Springs, Colo., and vicinity.

SIDNEY J. JENNINGS
President American Institute of Mining Engineers

Entertainment of Members and Ladies

A visit to the new subway workings gave an opportunity to see the methods of excavation and timbering employed in the hard rock of Manhattan Island and the glacial drift of Long Island. In the former case rock excavation was carried on for a new subway beneath one in which a train was passing on an average of every 30 seconds.

Mr. MARK R. LAMB exhibited motion picture views of Bolivian tin mines.

At the war smoker, which was presided over by Dr. A. R. LEDOUX, there were a number of interesting and inspiring addresses. Capt. R. HODDER-WILLIAMS of the British Expeditionary Force reminded the American people of the necessity of discipline, not only in our army but throughout the mass of the people. He was followed by a representative of France who expressed the gratitude of his people for the assistance now being rendered by the United States.

The work of the Fuel Administration was explained by S. A. TAYLOR and M. L. REQUA, the latter having recently been placed in charge of the oil division. Mr. W. L. HONNOLD spoke for the Belgian Relief Commission and explained that during the last six months it had been possible to supply only 60 per cent of the requirements of Belgium and northern France. A total of over $400,000,000 has been disbursed by the commission. The War Minerals Committee was represented by its Chairman, WILLIAM Y. WESTERVELT, who asked support for the bill through which Congress will be asked to grant powers to a mineral administrator.

On Wednesday evening the reception of the incoming and retiring presidents, and the "Hoover" dinner were held at the Hotel Biltmore. President Moore acted as toastmaster at the dinner and called upon Captain Dulieux of the French High Commission, W. I. Hotchkiss of the War Minerals Committee, Bainbridge Colby of the United States Shipping Board; W. S. Miller, geologist of Canada, and Sidney J. Jennings.

The Ladies' Auxiliary of the Institute took charge of entertainment of visiting ladies. On Monday visits were made to the art galleries of Henry C. Fricke and W. A. Clark. A motion picture exhibit of devastated regions in northern France was given on Tuesday, followed by a visit to the Metropolitan Museum of Art. In the evening President-elect and Mrs. Sidney J. Jennings held a reception at their residence. On Wednesday morning Dr. ALEXANDER CAIRNS, representing the Food Administration, gave an illustrated talk on "Feeding the Multitude," and was followed by a speaker for the Commission for Relief in Belgium. Wednesday afternoon there was a theater party for the ladies to see a performance of "Chu Chin Chow."

Trip to Princeton

Thursday was devoted to an all-day trip to Princeton University. Luncheon was served in Proctor Hall of the Graduate College, after which President Hibben of Princeton addressed the audience. He spoke of the fundamental, constructive nature of the work of engineers, not only in war but also in peace. President Moore responded for the institute.

The party was then conducted through the Ground

Aviation School and the scientific laboratories of the university and entrained for New York.

Session on Non-Ferrous Metallurgy

This session was held on Monday morning with G. H. Clevenger in the chair.

The Disadvantages of Chrome Brick in Copper Reverberatory Furnaces, by F. R. Pyne. This paper has already been published in our issue for Jan. 1, 1918, p. 20. The author had found hydraulically pressed magnesite brick preferable to chrome. In discussing the paper, Prof. H. O. Hofman said:

"The paper by Mr. Pyne gives clear evidence of the difficulties the metallurgist is likely to encounter when he tries to recover in the blast furnace the metal from old chromite lining used as a refractory material in the copper reverberatory furnace. It appears that chromite cannot be fluxed at temperatures which usually prevail in copper blast furnaces. This calls to mind the freezing-point curve drawn by M. Simonis of mixtures of chromite and kaolinite. (See *Stahl und Eisen*, 1908, Vol. 28, p. 335.) The chromite used in the experiments contained 52.9 per cent Cr_2O_3, 22.6 FeO, 4.8 Al_2O_3, 9.6 SiO_2, 10.1 MgO; the kaolinite was clay from Zettlitz with 98.5 per cent clay-substance. The eutectic mixture with 35 per cent kaolinite and 65 per cent chromite freezes at Seger cone No. 15 (1435 deg. C.), while kaolinite fuses at cone No. 35 (1770 deg. C.) and chromite at cone No. 42 (2000 deg. C.). The curve indicates that the difficulty in the blast furnace can be overcome by having at the smelting zone a temperature much higher than is usual in copper smelting; a charge composition similar to that prevailing at the Mansfeld copper smeltery—which gives with 23 per cent coke a slag of the composition SiO_2 49.09, (FeMg)O 5.58, (CaMg)O 16.02, Al_2O_3 16.02—might flux and fuse chromite."

Mr. Pyne said that ferrochromium could be made from the chromite and that his company had considered installing an electric furnace for this purpose, but the war had required their attention on other things. Mr. Clevenger said it had been his experience that chrome brick formed a poor furnace lining for electric furnaces operating at high temperature. Mr. Forest Rutherford said he agreed with Mr. Pyne on the metal absorption by chrome brick and on the difficulty of fluxing chrome bats. On the other hand, he said he had found magnesite unsatisfactory for reverberatory furnaces except in the roof. He had used at the Copper Queen Works, Douglas, Ariz., a lining consisting of a layer of magnesite, a layer of chrome and a layer of silica; the latter forming the inner furnace surface. Mr. Stoughton said it was patriotic not to use any more chrome brick than necessary on account of the shortage and the fact that there were certain places where it must be used.

Fine-grinding and Porous-Briquetting of the Zinc Charge, by Woolsey McA. Johnson. The author made some experiments with the idea of reducing the coal and coke used by charging finely-ground porous material. It was reasoned that such a charge could also be much more easily reduced and would have greater heat conductivity. From his experiments he figured a reduction in cost of $5.67, by means of increased charging, resulting from fine-grinding, ventilating and briquetting, assuming a cost of $17 per ton of ore. The reduction in "charge" coal cuts the cost of coal from $2 to $1.20. There would be a certain reduction in furnace labor and also in retort consumption because the charge gives a residue that blows out clean. The recovery will be increased because of low residues and decreased retort-consumption; perhaps this saving will amount to $3. The credits thus total $10.97 while the debit is $1.50; or a total net saving of $9.47 is possible. The briquetting needs a special binder. In the discussion Mr. O. C. Ralston said that the zinc smelters complain of the large amount of flue dust from roasting and that some such method as described by Mr. Johnson would be the solution of the problem. Mr. Hall of the New Jersey Zinc Company asked what binder was used and what per cent. Mr. Johnson said 10 to 12 per cent of sludge acid from oil refining gave good results.

High-Temperature Resistance Furnaces with Ductile Tungsten or Molybdenum Resistors, by W. E. Ruder. This paper described various types of furnaces developed by the Research Laboratory of the General Electric Company to meet the general needs of laboratory work. Since the discovery, by this laboratory, of methods for producing tungsten and molybdenum in ductile form, their use as resistance elements in the Research Laboratory of the General Electric Company has grown to such an extent that they are now almost indispensable. These furnaces are used here for alloy research, annealing, heat-treating, and practically all of the thermal processes requiring temperatures above 900 deg. C. In discussing the paper Mr. Spilsbury asked whether the furnaces were for laboratory purposes only. Mr. Ruder replied that they were, and had been developed originally for heat-treating tungsten. Mr. Hall asked whether the author had used reducing gases in such furnaces. Mr. Ruder said he found trouble getting a tube which would not leak gas at a high temperature.

Zinc Refining, by Leland E. Wemple of the American Zinc, Lead and Smelting Company, St. Louis, Mo. Mr. Wemple first discussed in a general way the impurities in spelter and methods of reducing same, and the need for high-grade spelter since the war began. He then took up redistillation methods which are in use and proposed, and also discussed refining by remelting and the grade of the refined zinc. In the discussion Mr. Spilsbury asked what the total loss was in redistillation, including lead, blue powder and the final remelting. Mr. Wemple said that approximately 5 per cent was lost on the first operation. This is a zinc loss. The lead should not be considered a loss, as it is finally recovered. The by-products run about 15 per cent, consisting of blue powder, skimmings, etc. About 3 per cent of this is scrap and the balance blue powder. The net loss is about 6 to 7 per cent of the zinc content of the charge. Mr. W. McA. Johnson asked what percentage of lead was carried over mechanically and what percentage by vapor pressure. The author had no data but said it was possible to produce zinc with only 0.03 per cent lead by running near the boiling point of zinc, but as the temperature goes higher the lead increases. If not careful 0.25 to 0.30 per cent lead can be produced. The essential thing to keep the lead down to low limits is heat control.

The other two papers presented at this session were *Bone-Ash Cupels*, by F. P. Dewey, of the Bureau of the Mint, and *An Automatic Filter at Depue, Ill.*, by G. S. Brooks and L. G. Duncan. A synopsis of Mr. Dewey's paper appears in this issue, page 260.

Session on Mining and Milling

Hints on Bucket-Elevator Operation, by A. M. Nicholas. This paper gave some practical hints from the author's experience. The settling of heavy pulp in the buckets, with consequent failure to discharge the load, was overcome by agitating the belt about midway of its span. The cutting of elevator belts by sharp rock was overcome by attaching a wooden shield below each bucket to prevent fine particles of rock from falling between the belt and the bucket when the latter passed over the head pulley. A balata belt thus equipped has been in use for two years and has hoisted about 50,000 tons of rock. The slipping of narrow high-speed belts can be prevented by using a belt made of small blocks of leather overlapping at the ends and pinned through with metal pins.

Recent Tests of Ball-Mill Crushing, by Charles T. Van Winkle. This paper was published in extended abstract in our issue for Jan. 15, page 207. It concerns tests of Hardinge & Marcy Mills. In discussing this paper Mr. Parke Channing stated that the problem presented to Hardinge and Marcy was to install crushing capacity for 1000 tons per day, each using two mills. The Miami staff had considered Mr. Hardinge unwise to attempt the test with less than three mills, and the unsatisfactory results obtained by him are attributed to his attempt to do the work with two mills. The original Miami mill had a set of rolls and two Hardinge mills for each section, but later they put three Hardinge mills in each section and the results were satisfactory.

In further discussion Mr. B. Britton Gottsberger submitted a concise statement of the work now done at Miami in a completed section, using three Hardinge mills for fine grinding.

The ore hoisted through the main shaft is dumped into a 1000-ton bin located at the head of the crusher plant. The plant consists of No. 7½ gyratory crushers followed by two sets of rolls 55 in. by 20 in. and 42 in. by 16 in., respectively, operating in closed circuit with trommels fitted with screens having ⅝ in. by 1⅛ in. slotted holes. Practically all of the product produced will pass a ¾-in. round hole, as shown by the average screen analysis for the month of January given below:

Table I.—Screen Analysis of Feed to Ball-Mills

	Per Cent	Cum. Per Cent
On ¾-in. round hole	1.1	1.1
On ½-in. round hole	13.8	14.9
On ⅜-in. round hole	13.7	28.6
On ¼-in. round hole	12.2	40.8
On 3/16-in. round hole	7.4	48.2
On ¼-in. round hole	9.3	57.5
On 10-mesh	8.3	65.8
On 14-mesh	4.4	70.2
On 20-mesh	3.3	73.5
On 28-mesh	4.0	77.5
On 35-mesh	2.4	79.9
On 48-mesh	2.7	82.6
On 65-mesh	2.0	84.6
On 100-mesh	1.5	86.1
On 150-mesh	1.9	88.0
On 200-mesh	1.3	89.3
Through 200-mesh	10.7	
	100	

The product of the crusher plant is carried by belt conveyors to the mill bins located back of each section of the plant with a total capacity of about 10,000 tons. From this point reduction of the ore is carried out entirely in Hardinge ball-mills, three of these machines being installed in each section to handle approximately 1000 tons per day of crusher plant product, which is ground to a point where practically nothing remains upon a 48-mesh screen. The mills used are built of cast iron and are 8 ft. in diameter by 36 in. length of barrel, driven direct by electric motors through Wuest gears. Each mill is equipped with a 150-hp. motor and runs at 20.6 r.p.m.

The grinding is at present done in two stages. The entire section tonnage is first subjected to single-pass crushing through one mill, the product passing to a 4-ft. 6-in. Dorr classifier. The overflow of the classifier is finished product. The sand product of the classifier, representing the oversize of the first mill, is divided equally between two mills of the same size, each operating in closed circuit with a 6-ft. Dorr classifier. The overflow of these classifiers is finished product, the sands being returned to the mills for regrinding. The product produced by this system of grinding is shown by the following average screen analysis of the tailing of Section 6 of the plant for the month of January, 1918:

Table II.—Screen Analysis of Hardinge Ball-Mill Product

	Per Cent.	Cum. Per Cent
On 28-mesh	.9	.9
On 35-mesh	1	1
On 48-mesh	.4	.5
On 65-mesh	3.8	4.3
On 100-mesh	14.2	18.5
On 150-mesh	14.8	33.3
On 200-mesh	6.3	39.6
Through 200-mesh	60.4	
	100	

The average tonnage handled in Section 6 by the three mills during the month of January, 1918, was 987 tons per day of 24 hours. The power consumed in grinding by the three mills according to wattmeter readings amounted to 7475 kw.-hr. per day, equivalent to 7.57 kw.-hr. per ton. The power consumption for the balance of the work done in the total reduction from mine rock is very small. We have no accurate wattmeter readings on this, but according to our regular power distribution, figured from ammeter readings, the power for preliminary coarse crushing, conveying and operation of the Dorr classifiers amounts to 1 kw.-hr. per ton. Therefore, the total power consumption from mine rock to finished product is 8.57 kw.-hr. per ton.

Theory and Practice of Ball-Milling with Peripheral Discharge Mills, by Pierre R. Hines. These notes were based on observations made by the author on a western trip made for the purpose of studying the ball-mill. He finds that balls fall from their maximum free height when the ball charge is about one-third the volume of the mill, and that the greatest number of tons crushed to a certain mesh per kw.-hr. is obtained under that condition. Capacity depends upon fineness of grinding, weight or volume of ball charge, hardness of material, size of grate openings and size of balls, other factors remaining constant. Tonnage and fineness are inter-related and the capacity of a ball-mill should be figured on the following basis when sufficiently reliable figures have been collected. The kw.-hrs. required to crush a ton of ore from and to a certain mesh should be arrived at from average operating conditions. A ball-mill has a certain definite maximum power rating depending upon its ball load. Multiplying the kw.-hrs. per ton by the tons required to be crushed per hour, the product will represent the power required, and the mill nearest to that power rating should be selected. For ball-mill feeding he recommends an apron feeder controlled by a variable-speed transmission device, and a smooth trunnion liner tapering into the mill. For fine grinding the best ratio of water to solids is 1:2 or 1:1½. Ball consumption varies with conditions of ore and grinding, but is about ½ lb. per ton for steel balls and 1 lb. for cast composition balls, when the product all passes 8-mesh and contains 10 to 20 per cent below 200-mesh, the mill running in open circuit. Average consumption of liners, for both chrome and manganese steel, is 1.3 lb. per ton of ore crushed, being fairly constant regardless of conditions.

New Method of Separating Materials of Different Specific Gravities, by Thomas M. Chance. This paper

was presented by Mr. H. M. Chance, who gave a demonstration with a small experimental device. The method is based on the fact that fine sand mixed with water can be maintained suspended in the liquid by continuous agitation, and that this agitated mixture will act like a fluid of high specific gravity, including its ability to float solid bodies of less specific gravity and permit those of greater specific gravity to sink in it. In the apparatus exhibited, agitation was produced hydraulically by pumping water through the sand, and a mixture of coal and slate was readily separated. The method is believed to be of wide application in the mineral industry, and is about to be applied in coal washing.

The last milling paper presented at this session, on the United Eastern Mill, by OTTO WARTENWEILER, was published in this journal, Dec. 1, 1917, page 656.

SESSION ON IRON AND STEEL

The Erosion of Guns, by HENRY M. HOWE. This paper is based on the examination of two rings from an eroded gun liner. It treats of the hardening of the bore by its rapid cooling by the outer metal, the cumulative cracking of the bore, and possible palliatives of erosion. The phenomena are explained by assuming a "temperature cycle," or course of heating and expansion in each round. Following is an extract of the author's summary:

> At any section the cycle begins with the passage of the driving band of the projectile, from which the lips of each crack, hardened in the preceding round and still cool, bite off a mouthful of copper, thus sealing themselves. Next comes extremely rapid heating, expansion, and closing of the cracks, with extrusion of much of the copper. A thin layer of the bore face is melted and swept forward by the rush of the gases, together with so much of the metal outside it as is heated to erodible mobility, the metal removed from any one section being thus replaced in part by that swept forward from rear sections, and this forward sweeping layer keeping all cracks sealed till the bore-face metal again hardens. With this forward sweeping probably goes the entrainment of some of the molten metal in the form of a mist, its bodily removal from the gun, and choke-boring. Thus the erosion at any given section consists first of this misty entrainment, and second of excess of metal swept forward from that section over that swept to it.
>
> In the heating period, brief as it is, some of the initially distinct particles of ferrite and cementite in a very thin layer adjoining the bore face merge to form austenite. The following cooling by conduction into the cold outer metal is so rapid that this austenite is caught in the state of martensite and is thus hardened. It is next annealed during the heating period of the next round and in part eroded and re-hardened in the following cooling. Thus the hardening is repetitive.
>
> The thickness of this hardened layer increases asymptotically from round to round, because the heating in each round extends beyond the layer actually hardened in the ensuing cooling, and in thus extending begins the merging of the ferrite and cementite beyond the layer hardened, and thus facilitates further merging and thus hardening in the next round.
>
> In the cooling of each round the layer which has been fluid or at least pasty cools and hence contracts much more than the outer and cooler metal with which it is integrally united, and thus becomes in effect stretched by the resistance of this strong outer cold metal beyond its ability to retain continuity, and thus cracks.
>
> In the grooves the expansion has to be axisward solely, and the cracking in the subsequent cooling is, therefore, about the same longitudinally as circumferentially. But the forward rush of the gases exaggerates the longitudinal cracks, so that the longitudinal ones are more prominent than the transverse. The expansion of the lands occurs both axisward and circumferentially, and the corresponding circumferential contraction in large part relieves the tendency to form longitudinal cracks, with the result that the main cracks are transverse.
>
> The copper stopping of each crack, and the oxidation of its sides during the period of contraction, cause the cracking to be cumulative, so that the total width of the cracks, including their copper stoppings, is about ten times that corresponding to the contraction occurring in a single round. The transverse cracks on the strongly pressed lands are so much more prominent than those in the grooves, and have such an approach to even spacing, as to suggest strongly that they are exaggerated by chattering.
>
> In the forward lands many of the cracks are filled flush with copper. The rest are black and not filled flush. A copper network projects from the forward grooves. The difference is referred jointly to the continuation of the expansion in the grooves till a later period than in the lands, and to less violence of the gas-rush in the grooves than on the lands, with the result that all the copper ejected by the expansion from the land cracks is wiped away by the gases, while the latest extruded from the groove cracks persists.
>
> The cracking of the bore probably neither hastens erosion nor weakens the gun.
>
> White-hardness and also great thermal conductivity, specific heat, and density, should lessen erosion.
>
> Of the palliatives of erosion, the replacement of the liner seems the most promising.
>
> Though experiments with other alloys of high melting point should be tried, the prospect of success is not great, because the available metals more infusible than iron are thought to yield alloys less infusible than it, and also difficult to machine, costly, and prone to oxidize.
>
> The success of manganese steel in pipe balls in resisting conditions closely like those of gun liners suggests experimenting with it.

Dr. Howe's paper was discussed at length by naval engineers and others, but lack of space prevents publication of the comments.

Transverse Fissures in Steel Rails, by J. E. HOWARD. This paper dealt with fractures in steel rails at right angles to their length. The author regarded them as a modified type of fatigue fractures of interior origin. He explained their occurrence in the light of common knowledge on the behavior of steel under repeated alternate stresses. "By reason of the state of internal compression at the running surface, the maximum tensile stresses in the head, under bending loads, were along an interior element. Here the tensile strains were higher than in the fibers, more remote from the neutral axis. Under such conditions the fracture of the rail would be expected to have an interior origin." The author further stated that neither chemical analysis nor microscopic examination showed a definite cause for development of transverse fissures, and that such fissures developed in rails structurally free from any known defect. The fissures are found where traffic, wheel loads and speed have increased and where these conditions are well advanced.

Considerable discussion was elicited by this paper. Mr. WEYMOUTH found that most rail failures due to transverse fissures occurred in rails of extreme chemical hardness, and suggested adopting rails of different compositions for specific duties. Mr. UNGER suggested the following remedies: (1) Proper support of the rail to prevent alternate stresses; (2) decrease of the load on rails, and (3) an increase in the section of rails. Dr. DUDLEY did not accept the author's conclusion of the origin of transverse fissures and did not believe they were fatigue fractures. Mr. RAY believed that mill practice greatly influenced the development of transverse fissures and thought more attention should be given to the manufacture. He had found that these fissures developed mainly in rails of 0.80 carbon or above.

Session on Metallography

This session was marked by the presentation of a number of highly technical papers which can scarcely be presented in brief abstract. Metallography is making rapid progress under the direction of a comparatively small group of brilliant investigators, and the metallurgical industry will find itself deeply indebted to them as time goes on.

Grain-Size Inheritance in Iron and Carbon Steel, by Zay Jeffries. The author elucidated the following general laws influencing grain size, and illustrated his discussion by citing actual examples.

The grain size of any transformation product in iron and carbon steel due to heating or cooling through the transformation range will depend on:

A. The rate of heating or cooling through the transformation range.

B. The grain size and arrangement of the constituents just prior to the occurrence of any transformation.

C. The chemical and physical composition of the iron or steel product, *i.e.*, carbon content, sonims, gas inclusions, blow holes, etc.

D. The temperature gradient obtaining during the transformation period.

The Time-Effect in Tempering Steel, by A. E. Bellis. The author discussed the relation of reheating to physical properties and machinability of steel, particularly rifle-barrel steel. Tests are cited to show that increasing the time of reheating increases the ductility, toughness and machinability of the particular steels described.

Some Structures in Steel Fusion Welds, by S. W. Miller. This paper is a discussion of conditions observed under the microscope in sections of oxy-acetylene and electric arc welds. It must be studied in connection with the microphotographs.

Effect of Copper in Steel, by Carle R. Hayward and A. B. Johnston. A synopsis of this paper appears in this issue, page 260.

Session on Employment Problems. A new departure was inaugurated at this meeting in the form of two sessions on employment problems. The growing importance of this subject has been realized by the institute, and programs were arranged covering all phases of the labor problem. Some of the points emphasized were the necessity of a thoroughly capable employment manager, adequate living conditions for labor and proper care of workmen while on duty. Other interesting topics concerned the training of workmen for better positions and the crippled soldier in industry. All of the papers are worthy of careful study.

Patent Office Improvements.—A composite committee has been created by the National Research Council to make a preliminary study of the problems of the United States patent office and its service to science and the useful arts. This committee comprises L. H. Baekeland, W. F. Durand, Thos. Ewing, Frederick P. Fish, Robert A. Millikan, E. J. Prindle, Michael I. Pupin, S. W. Stratton. Those interested in making any patent-reform suggestions are advised to forward them at once to Dr. Wm. F. Durand, National Research Council, Washington, D. C. The particular point upon which suggestions are desired is the manner in which greater efficiency and work of higher quality can be secured in the Patent Office.

Spring Meeting of the American Electrochemical Society

At a meeting of the board of directors of the American Electrochemical Society held in Philadelphia on Feb. 22 it was decided to hold the spring meeting in the South during the week of April 28. In accordance with plans previously proposed, the society will make a trip of one week through the chemical, electrochemical and metallurgical centers of the South. Over eighty members and guests have agreed to go. The society was urged by Southern members, heads of industrial concerns and railroad officials not to abandon this trip, all agreeing that it would afford a timely opportunity to study the present development and future resources of the South with respect to national needs. Railroad officials anticipate no difficulty in arranging transportation.

It is planned to leave Washington, D. C., Sunday evening, April 28, and spend one day in each of the following centers or districts: Kingsport, Knoxville and Chattanooga, Tenn., Sheffield and Birmingham, Ala. Programs of technical papers will be presented each evening. On the return trip the party will arrive in Washington Sunday, May 5, in time for individuals to reach their homes Monday morning. Arrangements are in charge of a committee headed by Mr. C. F. Roth, who may be addressed at Grand Central Palace, New York City.

Engineers in Government Service

THE Engineering Council, through its American Engineering Service Committee, has during the past few months supplied to various government departments and bureaus in response to their requests several thousand names of engineers from which men were to be selected to fill a great variety of positions in uniformed and civilian service for Army and Navy and other branches of the government's activities in connection with the war, as well as for indirect service for manufacturers and contractors engaged upon government war work.

To meet these demands the American Engineering Service Committee has assembled in its offices in the Engineering Societies Building, New York, extensive lists and much detailed information concerning engineers in all branches of the profession throughout the length and breadth of the land. It will readily be appreciated that if these lists are to be maintained in the most useful condition to the government and the Engineering Council, the committee should receive promptly information concerning each engineer who has gone into any kind of government service, direct or indirect, so that a record may be made on his cards in the committee's office.

Engineers reading these lines, to whom this request applies, are urged to send at once their names, present addresses and occupations in the government service, with brief statement as to whether or not they are available for other service, to American Engineering Service Committee, Room 901, 29 West 39th Street, New York. Other readers are asked to bring this request to the attention of such engineers or to send information directly to the committee at the above address.

Ultraviolet Energy and Its Use

By M. LUCKIESH
Physicist, Nela Research Laboratory

SINCE the discovery of ultraviolet rays, more than a century ago, their production and properties have been subjected to a great deal of investigation. However, notwithstanding the extensive literature on the subject, we must agree with Sheppard, who says in his book on Photo-chemistry: "We are only at the beginning of the conscious utilization of the powers of light, as distinct from the unconscious enjoyment of them." Owing to the many unique propties of these invisible rays they are extremely valuable in certain scientific investigations, tests, and industrial processes, and it appears certain that, with the progress of the development of sources of ultraviolet rays, and of media transparent to them, the usefulness of ultraviolet energy will be rapidly extended. The problems in which these unique properties may be utilized are so manifold, it appears that a general discussion of the subject may be welcomed at this time. For the sake of clearness in the following discussions, the spectrum will be divided arbitrarily, as follows:

Visible spectrum extends to wave-lengths slightly shorter than 400μμ.

Near ultraviolet will designate the region between 400μμ and 300μμ.

This may be said to be the extent of the ultraviolet spectrum ordinarily encountered because clear glass is, in general, opaque to rays of shorter wave-length.

Middle ultraviolet will designate the region between 300μμ and 200μμ.

Schumann region is that from 200μμ to beyond 100μμ. This region has been studied elaborately by Lyman[1], who has revealed the spectrum somewhat beyond 100μμ.

It is understood that some of these divisions and limits have been chosen arbitrarily for the sake of convenience in the present discussion.

Transparency of Media

The transparency of various media for ultraviolet rays is of importance from the standpoint of the production, measurement, and utilization of this energy. Enclosing media and optical parts must be transparent to the rays to be utilized. Ofttimes filters are desired for isolating certain spectral regions and in many other ways it is of interest to know the spectral transmission characteristics of various media. Of course, the thickness of the medium is an important factor, but where this is not mentioned in the following discussion, ordinary moderate thicknesses will be assumed. In this general discussion it is out of the question to take up this and many other details.

Clear glass varies in its spectral characteristic in the ultraviolet region, depending upon its composition. Most ordinary clear glasses are quite transparent down to 350μμ, but they usually decrease in transparency from this point until they become practically opaque at about 300μμ. The Jena works developed a glass (uviol) which transmitted quite freely down to 300μμ. Fritsch[2] has given a formula for a durable glass which he claimed to be transparent as far as 185μμ. He recommended 6 grams of $CaFl_2$ mixed with 14 grams of B_2O_3 in powdered form. This was melted in a platinum furnace crucible and poured out on an unheated sheet of platinum.

Fused quartz transmits freely to about 220μμ. Crystal quartz is transparent as far as 180μμ. It is thus seen that quartz is only useful for the middle and near ultraviolet regions.

Fluorspar is not only transparent to these regions, but also to nearly all the Schumann region, its transparency extending to 120μμ.

Air absorbs the rays in the Schumann region quite powerfully. Therefore, for most practical purposes quartz is satisfactory. An air-path 1 cm. long is opaque to radiant energy of wave-lengths shorter than about 170μμ. The solar spectrum, even when photographed at high altitudes, ends at about 290μμ, indicating the presence of media in the earth's atmosphere or in that of the sun which are opaque to the rays in the middle and Schumann regions. Lyman presents data on the absorption of gases which may be of interest in this connection.

Snow reflects the near ultraviolet rays almost completely.

A thin veil of smoke is opaque to the middle and Schumann regions.

Gypsum, celestite, borite, sugar crystals, calcite and alum are opaque to most of the Schumann region, their transparencies ending in the neighborhood of 170μμ.

Mica strongly absorbs the rays of short wave-length.

Rock salt is of high transparency at 185μμ.

Gelatine strongly absorbs the rays of shorter wave-length than 200μμ and therefore, for photographic work in this region, non-gelatine plates must be used. It is obvious that an evacuated space also must be provided owing to the absorption by the air.

Pure water is quite transparent to the middle and near regions.

The above-mentioned substances are of interest largely owing to their transparency but certain filters are of special interest owing to their spectral absorption characteristics.

Many optical glasses which are nearly colorless or of a yellowish-green or yellowish tint effectively absorb nearly all the ultraviolet region. Uranium glass is very effective in this respect and by virtue of its fluorescence it is useful in exploring an ultraviolet spectrum especially for such a purpose as focussing a spectrograph. Quartz spectroscopes are sometimes equipped with such fluorescent screens in the eye-piece for visually inspecting the ultraviolet spectrum. A solution of quinine sulphate or of aesculine effectively absorbs the ultraviolet rays and both fluoresce.

Dense cobalt-blue glass combined with an aqueous

[1]Spectroscopy of the Extreme Ultraviolet. Longmans, Green & Co., 1914.

[2]Phys. Zeit. 8, 1907, p. 518.

solution of $CuSO_4$ (which absorbs the red band transmitted by the cobalt glass) isolates the near ultraviolet and violet rays.

Nitroso-dimethyl-aniline dissolved in water is fairly transparent between 280μμ and 400μμ. This may be incorporated in gelatine (6 grams of gelatine to 100 grams of water heated to about 50 deg. C.) and flowed on a glass or quartz plate. The best strength of this filter is one which just eliminates the blue and violet light. This filter may be combined with blue uviol glass and an aqueous solution of $CuSO_4$ for the purpose of isolating the near ultraviolet. In case the glass elements of such a combination are unsatisfactory, quartz plates may be used and a dense solution of methyl violet or other deep violet dye may be substituted for the blue uviol glass.

Many combinations of aniline dye solutions or gelatine filters may be used for isolating the near ultraviolet.[3] For isolating portions of the middle and Schumann regions various gases and other media may be used. For example, Peskov[4] studied the spectral absorptions of chlorine and bromine and found that, by varying a mixture of these two gases, he could isolate regions of the spectrum as narrow as 240μμ to 250μμ. These mixtures were found to follow Beer's law and, therefore, after having obtained the requisite quantitative data, the mixture for filtering a certain spectral range could be calculated.

Metallic silver is opaque to the ultraviolet except for a narrow range near 300μμ to 340μμ. Colloidal silver appears to have a spectral transmission characteristic which differs from that of the metallic film.

Absalom[5] dissolved such metals as K, Na, Li, Cs, Rb, Ba, and Sr in ammonia and obtained blue solutions which had valuable properties as ultraviolet filters. These solutions were quite fugitive but with dry ammonia and freshly scraped metal, Cottrell obtained blue solutions lasting as long as several years. A general result of Absalom's work was that transparency far into the ultraviolet is much more commonly met with in the case of color due to colloidal metals than in the case of ordinary colored salts or aniline dyes. The limit of transmission for liquid ammonia is at about 240μμ. In general for these blue solutions total absorption began in the neighborhood of 245μμ.

Absalom used an arc between copper poles and a small quartz spectrograph and thus was able to photograph a spectral range between 500μμ and 225μμ. He presented the following wave-lengths in μμ as those at which complete absorption commences:

Natural blue rock salt	Beyond 225 μμ.
Natural rock salt colored by cathode rays	Beyond 225
Natural rock salt colored blue by cathode rays	Beyond 225
Sylvite, white	Beyond 225
Chili saltpetre, ordinary white variety	351.2
Chili saltpetre, violet	324.8
Fluorspar, colored deep violet by cathode rays	Beyond 225
Diamond yellow	320
Diamond blue	315
Kunzite	305
Garnet	402.3 μμ.
Zircon (hyacinth) red-brown	261.8
Zircon, decolorized by heat	244.2
Zircon, green	402.3
Zircon, yellow	402.3
Topaz, pale yellow	261.8
Topaz, dark yellow	229.4
Topaz, pale pink-brown	261.8
Topaz, blue	296.1
Emerald	320
Ruby	300
Tourmaline, green	351.2
Tourmaline, green-yellow	300
Tourmaline, pink	306.4
Spinel, blue	402.3
Spinel, purple	324.8
Spinel, pink	300
Kyanite, blue	320
Beryle, blue	327.4
Cordierite, blue-purple	324.8
Cairngorm	324.8

Sources.

There are many sources of ultraviolet energy but few are powerful enough to be widely useful. The ideal source, which emits a continuous non-banded spectrum of high intensity throughout the entire ultraviolet region, does not exist.

The incandescent solids such as the latest Mazda lamps emit a continuous spectrum of appreciable intensity through only a part of the near ultraviolet region. The sun emits a continuous spectrum of fair intensity as far as 295μμ but this spectrum has many dark lines due chiefly to selective absorption by the sun's atmosphere.

The limelight and burning magnesium ribbon emit appreciable ultraviolet energy but not in sufficient amounts to offset the inconvenience attending their use. Of the present-day sources this leaves only the arcs, sparks, and vacuum tubes available for the more general work.

The mercury arc in glass is obviously limited in usefulness by the absorption of the glass. Consequently the mercury arc in quartz tubes is much more applicable to ultraviolet work. This arc has the great advantage of steadiness but the disadvantage in some cases of large gaps in its line spectrum. Investigation has shown that the output of ultraviolet energy decreases materially with the time that the arc has been used, some old quartz mercury arcs being only half as effective as they were when new. However for many problems this arc is very satisfactory.

The ordinary carbon arc emits a considerable quantity of ultraviolet rays in the near and middle regions but there are other arcs which are far superior to it and are no less convenient to use. The magnetite arc has a positive pole of copper and a negative pole consisting of a sheet steel tube packed with a fine powder consisting principally of oxides of iron (magnetite), titanium, and chromium. This arc is fairly rich in ultraviolet rays.

Measured from the standpoint of total ultraviolet energy per unit of visual intensity of illumination, Bell[6] ranks these sources in the following order: magnetite arc, old mercury arc, new mercury arc, and car-

[6] Elec. World, Apr. 13, 1912

bon arc, the last two being about equal on this basis and more than twice as rich in ultraviolet rays as the first two. This basis is of interest in lighting but it should be noted that, in general, the ultraviolet output per watt of energy input is generally of interest.

Some spectra of interest will be found in Reference 3 and many emission spectra are to be found in the Atlas of Emission Spectra by Hagenbach and Konen. Atlases of absorption spectra have been prepared by Uhler and Wood and by Mees which show the absorption spectra of many soluble coloring media.

Lyman[1] has shown that the mercury arc emits a strong line near 185$\mu\mu$ which will be very effective, in some reactions, with a short air-path but only feeble with a long air-path owing to the absorption by the air. This indicates that, when dealing with radiation of such short wave-lengths, very different results may be obtained with the same source depending upon the distance of the reaction from the source.

The flame arc has potential possibilities as a source of ultraviolet rays owing to the diversity of materials with which the carbons may be impregnated. It has been found that the feebly luminous flame of the ordinary carbon arc is the source of much of the short-wave ultraviolet energy emitted. The white-flame arc of high amperage, in proportion to the energy input, is the most efficient commercial source of near and middle ultraviolet energy available at present. It radiates energy quite extensively in the near and middle regions. Mott found the fading effect on dyes at a distance of 10 inches from a 28-ampere white-flame arc to be several times greater than June sunlight and that the fading results were approximately the same. Obviously there should be no rays present of shorter wave-length than 295$\mu\mu$ in a dye-testing illuminant if the results are to be comparable with that of sunlight. Such a source as the white flame arc could be screened by a thin glass shell of a proper spectral transparency in order to eliminate rays of those wave-lengths not found in daylight.

The blue flame arc emits ultraviolet energy very strongly.

It is a simple matter to construct an arc which will emit ultraviolet energy strongly, provided hand-control is satisfactory. An iron rod and a carbon rod may be employed successfully for the two poles, however, two iron rods may answer the purpose very well. These poles may be kept cool effectively by means of heavy brass or copper sleeves which may be moved along the iron rods as the latter are consumed. A particularly successful iron arc of this type can be made in a few hours. The upper pole, which is negative, may be an iron rod about ¼-in. in diameter. This is surrounded by a movable but well-fitted solid sleeve of copper about one inch in diameter. The lower pole may be an iron rod about ½-inch in diameter with the end in the form of a shallow dish. One pole should be adjustable vertically. In preparing the arc a bead of molten metal is developed in the dished end of the lower electrode, the latter becoming oxidized, which apparently decreases the rapidity of deterioration. The upper electrode is well cooled and the arc is maintained very steadily between the molten bead of iron and the upper solid electrode. The writer has had such an arc operate at a rather high current density for thirty minutes without any adjustment. The dimensions may be increased to meet the requirements. It is not a difficult matter to make various simple arcs which are quite satisfactory for a great deal of work.

For many purposes the spark between metallic electrodes is very satisfactory but, in general, the sparks can not compete with the arcs in quantity of ultraviolet energy emitted. Various forms of spark gaps have been employed depending upon the requirements; usually steadiness of position of the spark and shadows of the poles are the factors which determine the shape of the gap. A short spark obtained from a transformer may be satisfactory or it may be fattened by using a condenser. A high frequency spark may sometimes be desirable. The kind of spark obtained depends upon dimensions and electrical relations and obviously these may be widely varied. The metals commonly employed for the poles of spark gaps are aluminium, zinc, iron, copper, and cadmium, although any other may be satisfactory, depending upon its spectrum and upon the specific requirements.

The spectra of electrically excited gases confined at low pressures in transparent tubes have been extensively studied but such vacuum discharge tubes have found little or no use in industrial processes. They have provided sources of extreme value in some investigations. The spectrum of hydrogen under these conditions exhibits many lines and bands in the Schumann region. These tubes are usually of the capillary type and contain the gas at low pressures of the order of magnitude of one mm. of mercury. Obviously, in order to be useful in the extreme short-wave region, they must be provided with a fluorite window.

Lyman[8] has studied the spectra of various gases in the Schumann region. It is interesting to note that the character of the circuit and discharge influences the spectra of some gases very much. For example, argon yields no lines shorter than 190$\mu\mu$ in wave-length with no capacity in the circuit. By using a disruptive discharge a considerable number of lines appear throughout the Schumann region.

Properties.

The effects of ultraviolet energy are too numerous to discuss at length in this article but a few will be noted briefly. The chemical changes in silver salts are well known and have formed the basis of the extensive developments of photography. Draper enunciated a law for photo-chemical reactions which states that only the light absorbed is chemically active. The converse of this law—that every substance which absorbs light undergoes chemical change—apparently is not true. An aqueous solution of an inorganic salt, for example, $CuSO_4$, strongly absorbs yellow and red rays but is not altered chemically by these rays. Bichromate salts which absorb blue, violet, and ultraviolet rays are stable by themselves but in the presence of organic substances the bichromate is reduced, that is, photo-chemical action obtains.

Ultraviolet energy is in general superior to visible rays in the production of fluorescence and phosphorescence. In fact under powerful ultraviolet rays it is almost impossible to find substances which do not fluor-

[1] W. R. Mott, Amer. Electrochem. Soc., 1915. Mott and Bedford, Jour. Ind. and Eng. Chem. 8, 1916, 1029.

[8] Astrophys. Jour. 3, 1911, p. 98.

esce to a slight degree at least. One of the most interesting experiments is found in focussing an intense ultraviolet spectrum in a horizontal position in space and bringing various substances in this plane. In this position the surfaces of solutions such as aniline dyes may be brought into the focussed spectrum. It is very interesting to note the rays which are most effective. In the case of phosphorescent materials, the regions which cause fluorescence alone may readily be distinguished from those which produce the more permanent glow. Even different colors of the resulting luminescence may be distinguished at different spectral regions of the exciting radiation. According to Sheppard, all organic bodies possessing strongly marked absorption bands in the ultraviolet, seem capable of either fluorescence in a dispersed condition or phosphorescence in a condensed condition when excited by ultraviolet energy of a proper frequency or wave-length. There have been applications of luminescent analysis to mineralogical and botanical research. This entire field of phosphorescence and fluorescence offers many opportunities for pioneer investigations.

When polished metals, such as zinc, are illuminated by ultraviolet energy they become positively charged if insulated. If negatively charged they become discharged. Under the influence of the rays, negative electrons are discharged from the metal. The breakdown voltage of an air-gap is decreased when illuminated by ultraviolet rays. Some of these phenomena may be accounted for by the ionization of the air but many metals emit electrons under certain conditions when illuminated by ultraviolet light of sufficient intensity. This latter effect is known as the photo-electric phenomenon. Even the dust particles in the air exhibit this photo-electric effect. The alkali metals are especially sensitive in this manner to visible rays as well as to ultraviolet rays. The photo-electric cell has become a valuable measuring instrument for those rays to which it is sensitive.

Ultraviolet energy is of interest from the standpoint of the permanency of coloring media because it is especially destructive in this respect.

Lithopone is darkened by these rays as is easily seen by projecting an intense ultraviolet spectrum upon a lithopone surface. By using quartz lenses and projecting the image of an arc on such a surface, the darkening was perceptible almost instantly, although it required many minutes of summer sunlight to cause the same darkening. This is a simple method of obtaining an intense concentration of ultraviolet energy which is useful in many processes and tests.

Ultraviolet energy accelerates the chlorination of natural gas in the manufacture of chloroform and hastens other processes. Blue and violet light are also effective in causing or hastening many chemical reactions.

Short-wave energy even in the near ultraviolet region is effective in changing the color of glasses especially those containing manganese. Under the influence of the radiation from the mercury arc some of these clear glasses containing manganese will assume a purplish tint after a few hours of exposure.

Ozone is readily produced in the vicinity of a powerful source of ultraviolet. It is believed by some that the solar spectrum ends at about 295$\mu\mu$ on the short-wave end, due largely to ozone which absorbs maximally at 255$\mu\mu$. Of course, smoke and various gases play some part.

Pure water is quite transparent to the near and middle regions but tap water is ordinarily slightly absorbing. Pidduck[8] studied very dilute solutions of salts commonly found in tap water and found distinctly different transparencies for ultraviolet although the absorption was not very great in any case.

The ionization of air by ultraviolet rays has led some to believe that the electrons or ions provide nuclei for the condensation of water vapor and thus ultraviolet energy may play a part in rainfall. Dust particles may very well serve as nuclei, and in this connection the classic experiment of artificial production of clouds by providing various kinds of nuclei is interesting.

Ultraviolet energy is very powerful as a bactericidal agent, the disinfecting property of sunlight being one of the first principles of hygiene and sanitation. Consecutive days of rain, mist or fog permit the growth and development of pathogenic organisms.

Owing to the transparency of water to the ultraviolet rays emitted by the quartz mercury arc, the latter is in use for killing germs in water. The water is usually filtered if it contains much solid matter in order that germs may not escape death in the shadow of a suspended particle.

Some medical authorities believe that ultraviolet rays are of greater value as a curative or bactericidal agent when associated with the blue and violet rays or even with the whole spectrum.

The effect of ultraviolet energy upon animal tissue is indicated by the bronzing of the skin and especially by the destructive effect upon the membranes of the outer eye. The cornea is opaque to all rays of shorter wave-lengths than about 295$\mu\mu$, therefore none but the near ultraviolet rays can reach the retina. But the lens is not transparent as far into the ultraviolet as the cornea. Owing to the industrial processes, such as acetylene and arc welding, which are attended by powerful ultraviolet energy, there is a demand for eye-protecting glasses. To develop such glass and to test the finished product, spectroscopy of the ultraviolet is necessary. Visual inspection cannot be depended upon for determining the satisfactoriness of eye-glasses in absorbing the ultraviolet rays.[9]

Measurement

Although much valuable information can be obtained by qualitative experiments, ofttimes it is necessary to measure at least the relative amounts of ultraviolet energy. There are many methods available; in fact, many of the properties of ultraviolet rays may be employed in measuring the intensity of the invisible energy provided a relation between effect and intensity is established.

The photographic plate is perhaps more generally used than any other method. Relations between intensity of the radiation, exposure, and photographic action or plate density must be established for the radiation to be measured. Owing to the opacity of gelatine in the Schumann region it must be eliminated

[8] Phil. Mag. 17, 1909, p. 710.
[9] Luckiesh, Trans. Illum. Eng. Soc. 9, 1914, 472

or greatly reduced in amount if this region is to be investigated photographically. Schumann adopted a special process of making silver bromide emulsions very weak in gelatine. His plates were sensitive to the short-wave region but not to radiant energy of longer wave-lengths than 300μμ. The photographic plate is perhaps the only means used for detecting ultraviolet energy of the shortest wave-lengths.

For certain regions the electroscope has been employed because of the leakage of its charge when connected to a piece of clean zinc which is illuminated by ultraviolet energy.

The photo-electric cell is sufficiently sensitive for spectral analysis in the near and middle regions but the relation between current and intensity of radiation must be established for the cell used. When cells are made according to certain specifications this relation has been found to be linear.

If the ultraviolet energy is sufficiently intense its heating effect may be used as a basis of measurement. In such a case the bolometer, radiomicrometer, and thermopile may possibly be sufficiently sensitive under the best experimental conditions.

Owing to the large number of photo-sensitive reactions it is possible to devise various methods of measuring ultraviolet energy, at least relatively, for certain ranges of the spectrum depending upon the reaction chosen. These are too numerous to be discussed at length here.

It has been the aim to review the subject in general as it might interest the chemist. In doing this within the limits of a single article it has been impossible to discuss many aspects and excellent researches; however, in the few references given will be found many others which will aid those who wish to pursue the subject further.

Problems of Wage Payment

By H. N. STRONCK

ONE of the most serious problems which industry is facing to-day is the problem of labor. Never before in the recent history of this country has there been such a scarcity of labor of all kinds, both skilled and unskilled. There is no outlook at the present time for an increase in the total number of labor units in this country, but there is every possibility that the scarcity will become greater and greater as time goes on and greater demands are made on the labor supply for Government service. The rate of wages in most industries is from 20 to 60 per cent greater than during the pre-war period and the effectiveness of labor at these much higher prices is far less than it was two or three years ago. To make matters worse, certain types of industries are able to give a much higher proportionate increase in wages than other concerns not so fortunately situated. As a result very keen competition has arisen in obtaining and holding labor of all classes from the highly skilled to the most ordinary type.

Objects to Be Attained

The majority of industrial managers are aware of this situation and can see far enough into the future to realize that some very strenuous efforts must be made to stabilize these conditions, to meet the ever increasing wage scale and to obtain a labor turnover as small as possible. The problem resolves itself into three parts:

(A) To hold the present working force intact.

(B) To be able to obtain and hold additional workers.

(C) To establish intensive training and co-operative methods so as to obtain the highest possible effectiveness of each labor unit.

Recent Plans

In order to hold the present working forces intact three general plans have come into vogue during the past year:

(A) The payment of a so-called service bonus.

(B) Insurance policies for workers.

(C) Betterment of working and housing conditions.

Service bonuses are generally paid as a percentage of the present wages, and vary with the length of continuous service. A very popular one is the payment of a 10 per cent bonus at the end of every three months for continuous service during the period. Other popular ones are based on a sliding scale of 5 per cent for three months' service, 7 per cent for six months' service and 10 per cent for one year's service. The contention is that the average worker employed in such an industry will at least remain the full length of the service period. In some industries the majority of the departments are on some type of production payment plan, and in such departments or groups where conditions are such that a production plan cannot be introduced a service bonus is paid above the nominal wage scale in order to equalize the wages throughout the plant. Service bonuses have a good effect on the older employees and especially on such employees who have their homes established in that community. Service bonuses, however, do not have a very great effect on obtaining new labor especially of the nomadic class, who are easily influenced to shift when they find that higher base wages are paid in their line of occupation in other plants, even though these plants be located at some distance from the community. Service bonuses as a rule do not act as an incentive for increasing production, and hence one of the greatest objects to be desired is not attained.

Life insurance policies for workers have become very popular during the past year. The amount of insurance taken out for a worker and paid for by the company is usually based on the yearly wage of the employee and the number of years of previous service in the plant. This form of reward acts well on the older and more settled employees who have families or de-

pendents, but has practically no effect on new labor or on younger employees with no dependents. Insurance rewards do not act as a strong incentive or argument in the obtainment of new labor units.

With the advent of the dilution of male labor with female it has become necessary to arrange for far better working conditions. Otherwise no very strong bid can be made for obtaining and holding female employees for ordinary plant operations. The general effect of improving working conditions is very good. It eliminates certain frictions and grievances and the general tone of the plant is raised to a higher level.

Production Rewards

The desired result in all industries is to:

(A) Obtain maximum production from each unit of labor.

(B) Pay higher wages than those paid in competing labor markets.

(C) Have the lowest possible direct labor cost per unit of production.

(D) Keep wastes of material at a minimum.

(E) Have all methods work toward the ultimate benefit of both employer and employee.

The advent of systematic cost-accounting methods must be credited as being one of the most important influencing factors for the introduction of wage payment plans based on production and waste elimination. Cost-accounting methods analyze and bring to the attention of the management true present costs and abnormal conditions of cost. Knowing the present cost, it then becomes the desire to reduce these. As a result a great many methods, plans and schemes have been evolved and introduced for the attainment of this object.

The management soon realized that the most wasteful and ineffective method of wage payment was the day-work method. Therefore, day-work methods must be replaced by methods which are based on reward for effort expended. The chief difficulty encountered was in the design of some plan whereby the effort of practically all employees could be measured and the reward paid accordingly.

Profit-sharing plans were introduced as far back as 1842, had a good effect in certain instances, but in general did not attain the object desired because they did not include certain fundamental principles necessary for success.

Essential Points of Wage Systems

Any system of reward to be highly effective must have the following points:

(A) The reward must be a definite and positive gain to the individual.

(B) The reward must be definitely known before the work is commenced.

(C) The reward must be personal; that is, the reward must be for that particular person, for that particular work.

(D) The individual must get exactly what was determined before.

(E) The individual must be positively assured that he will get the reward.

(F) As soon as the work is done the individual must get the reward.

Piece Work

Piece work, which was the most popular method until the efficiency movement reached its height, met the majority of these points. There is nothing wrong with the piece-work system in itself, but so many violations have taken place in the fundamental principles that the objects to be desired were not reached. Considerable dissatisfaction, grievances and many strikes have taken place. Piece-work methods are looked upon with great suspicion by the working classes. Regardless of whether or not piece prices have been cut in any particular plant, the inherent suspicion against piece work still remains in the minds of the workers, and one of the greatest of industrial wastes, the limitation of output, has been the result. With the present great fluctuations in labor market conditions it would hardly be advisable to introduce the very inflexible piece-work schemes. When it becomes necessary to pay higher wages, piece prices must be raised. If labor prices should decline, the only way the management could take advantage of this would be to reduce the piece prices. Also the principles of straight piece work do not guarantee a living wage. With the present ineffectiveness of labor and the introduction of female workers in industries, it becomes highly essential that, regardless of the output at the start, at least a guaranteed wage must be paid in balance with the daily wage scale in that district. From the standpoint of the management a piece price definitely fixes the direct labor cost per unit and there is no way of reducing the labor cost with high production unless the piece prices are cut.

Bonus Plan

Since the desired object was not attained by the piece-work, profit-sharing, contract methods, etc., new methods have come into vogue, many of which have been very successful and have replaced the plans previously referred to.

Bonus systems in general are based on the principle of dividing the savings effected in some definite proportion between the management and the employees. The majority of these guarantee an hourly wage, specify some definite standard of output and pay a bonus, in some cases when this standard is reached, and in a good many others when this standard is exceeded. The accompanying Chart I compares various forms of the best known and the most popular wage-payment plans.

Comparison of Various Methods

In making this comparison certain assumptions were necessary due to the fact that different standards must be set for each type of plan in order to produce the same amount of remuneration for the same output at a certain point. In determining standards for any type of production wage-payment plan the two following questions must be answered:

(A) How much work can be performed by a first-class worker at a speed under which he will thrive?

(B) What extra inducement must be paid to this first-class worker for this output?

On the particular case in point it was found by a long series of experiments and by time and motion study that a first-class worker could produce 148 units of output per hour and deliver this output day after day and month after month without injury to himself. It was

also found that a reward of 30 per cent above the wage scale was necessary to induce the worker to produce this output. The normal wage scale on this operation was 20c. per hour. Therefore, for an output of 148 units per hour it became necessary to pay a bonus of 6c. per hour, or a new rate of 26c. per hour. Regardless of the wage-payment plan, this worker must receive 26c. per hour for an output of 148 units per hour. All curves must intersect at point "Q."

HALSEY 33⅓ PER CENT PREMIUM PLAN (WAGE LINE GH)

Under this plan the worker receives as a bonus one-third of the value of the time saved. Example: If a worker's rate is 20c. per hour, a standard of 10 hours is set on a job, and the worker performs this in 7 hours, thus saving 3 hours, he would receive as a bonus one hour's time.

Because of the small part of the value of time saved paid as a bonus, the standard under this plan would necessarily be very low. As shown on this chart the standard would be 57½ units per hour and at an output of 148 units per hour he would receive the 30 per cent extra inducement.

Owing to the fact that the workers' share of the savings is small, no great investigation is necessary to determine standards under this plan. In general under this plan the standards are estimated from previous costs, and as a worker reduces these costs he receives one-third of the savings.

HALSEY 50 PER CENT PLAN (WAGE LINE FL)

Under this plan the worker receives as a bonus one-half of the value of the time saved. Example: If a standard of ten hours is set on a job and the worker performed this in seven hours, thus saving three hours, he would receive as a bonus 1½ hours' time.

Because there is a larger part of the value of the time saved paid as a bonus to the worker under this plan than under the Halsey 33⅓ per cent, the standard set would need to be greater Referring to the chart it will be seen that the standard under this plan would need to be 88 units per hour to bring the intersection at point "Q."

A greater intensive study of conditions and outputs must be made under this plan than under the Halsey 33⅓ per cent. In a great many cases the standards under this plan are based on time study, while in many others they are based on previous estimates of cost, and as a worker reduces these costs he receives one-half of the savings.

THE TAYLOR SYSTEM (WAGE LINE RQN)

Under the Taylor system two piece prices are set, known as the low rate and the high rate. Under this comparison the high rate is 30 per cent greater than the low rate. The standard set would be 148 units of output per hour. For outputs less than this amount the piece price would be 20 per cent less than for an output of 148 units per hour or more. Under this system the reward is great when the standard is reached, but for a failure to reach this standard the penalty is severe. Under this plan only a first-class worker can reach standard and thus obtain the bonus. Under present industrial conditions of ineffectiveness of labor units but very few workers in the ordinary plant would be able to reach the high reward under this plan. If it were possible to fill a plant at the present time with first-class workers this method of payment would act as the strongest possible form of incentive, but it would be far too difficult to introduce under present industrial conditions. Less than 10 per cent of the workers in the ordinary establishment would be able to take advantage of the high reward offered. Under this system great precision in rate setting and utmost standardization of operations are necessary.

GANTT SYSTEM (WAGE LINE XRQN)

The Gantt standard is the same as the Taylor; that is, 148 units of output per hour. Under this plan, however, applied to the case in point, an hourly wage of 20c. would be guaranteed regardless of the output. If the output reached 148 units per hour a bonus of 30 per cent would be paid.

Under this system the penalty for not reaching the output of a first-class man is not so severe. All workers are at least guaranteed a standard wage. The standard under this system must be set very accurately and conditions must be highly standardized. Only first-class operators would receive a bonus and hence such a system would effect but a small proportion of the employees in a plant under present industrial conditions.

STRAIGHT PIECE WORK (WAGE LINE AN)

Under straight piece work a definite price per piece would be paid regardless of the output. Under the case in point the piece price would be 0.176c.; that is, for an output of 148 pieces 26c. would be paid. If the output were less than 114 pieces per hour the worker would receive less remuneration than under any of the plans where the hourly rate is guaranteed at 20c.

THE EMERSON EFFICIENCY SYSTEM (WAGE CURVE BP)

Under the Emerson system the standard would be 138 units. A bonus of 20 per cent is paid, and the worker would receive 24c. per hour. The Emerson bonus, however, commences at efficiencies of 66⅔ per cent, so that if the output exceeds 108 units per hour, some bonus is paid. The proportion of bonus paid takes the form of a parabola from the 66⅔ per cent point to the 100 per cent or standard point. After the 100 per cent point has been reached, in addition to the 20 per cent bonus at 100 per cent, an extra 1 per cent bonus for each 1 per cent of efficiency increase above 100 per cent is paid. Example: If the efficiency is 110 per cent the bonus is 30 per cent.

The Emerson system is one of the most modern developments of bonus systems, has been given wide publicity through the writings of Mr. Harrington Emerson and has been applied in a great number of plants.

The standard under the Emerson system must be set with considerable care, as under the Gantt and Taylor systems.

ROWAN DIMINISHING PREMIUM SYSTEM (WAGE LINE CK)

This illustrates a typical diminishing premium system whereby rates are automatically cut at higher outputs. As under the others, a standard time is set and the worker receives his hourly wages for the time actually engaged on the job plus a premium figured on the actual time in proportion to the time saved to the

standard time. The formula for calculation of wages is

$$\left(\text{Time taken} + \left\{\frac{\text{standard time—time taken}}{\text{standard time}}\right\} \times \text{time taken}\right) \times \text{hourly rate} = \text{Wages.}$$

Under this system the worker can never double his day wage, as the value of the controlling factor, which is

$$\frac{\text{Standard time—time taken}}{\text{Standard time}}$$

constantly approaches unity as the time consumed approaches zero. Hence, the premium can never exceed the day rate multiplied by unity. Under this system the workman soon learns that above a certain output the reward is not sufficient to warrant the extra effort on his part. Because of this, limitation of output is very frequent under this system. This system has been in use in a number of plants, but because of its many disadvantages was discontinued and replaced by more equitable plans.

There have been various modifications of the original Rowan plan and in many the decrease in price per piece has been much more rapid. By comparing diminishing premium plans with any equitable plan it will be noticed that a zone is formed between the diminishing premium curves and any of the curves of the equitable plans. Louis Ruthenburg of the Dayton Engineering Laboratories Co. (Delco), after an exhaustive study of a large number of payment plans, named this zone the "Zone of Deception."

Where this plan had been introduced the management had the feeling that it was impossible to set accurate standards and their fear was that workers would earn too high wages. With the advent of scientific rate setting by time and motion studies the danger of inaccurate standards has been eliminated so that there is no justification for introducing any diminishing premium plans.

As will be noticed from the chart, the standard set for the case illustrated would be 105 units of output per hour.

THE BENEDICT-STRONCK DIFFERENTIAL TIME BONUS SYSTEM. (WAGE CURVE EM ¼ PER CENT PRINCIPLE—WAGE CURVE DO ½ PER CENT PRINCIPLE)

In formulating the principles and designing the application of these systems the object in view was to include the strong features of other wage systems and eliminate as many as possible of the weak points. The results obtained in practice by these methods have proven that this object has been attained.

These systems are based on certain fundamental principles and the design of the curves vary for different conditions without violating the fundamental principles. The fundamental principles on which these are based are:

(A) Guaranteed hourly rate known as the "base rate" below which the worker does not fall.

(B) A time allowance for each job known as the "standard time."

(C) A division of the value of the time saved from this "standard time" between the worker and the management on an increasing differential basis, in favor of the worker; that is, the greater the output the greater will be the proportion of the value of the time saved given as a bonus to the worker.

CHART 1. COMPARISON OF WAGE-PAYMENT PLAN

The accompanying Chart II illustrates the details of the Benedict-Stronck differential time bonus system on the ¼ per cent principle. This illustration is designed according to the following mathematical principles:

For efficiencies of between 100 and 125 per cent the worker receives as a bonus one-half of the value of the time saved. This is equivalent to the Halsey 50 per cent principle.

For efficiencies above 125 per cent the worker receives as a bonus, in addition to half the value of the time saved, ¼ per cent of the value of the time saved for each per cent of efficiency increase above 125 per cent.

As will be noted, the differential parabola is connected with the 50-50 line at the 125 per cent point. The following two examples illustrate the detailed calculation of the new hourly rates:

(A) For a point less than 125 per cent in efficiency. (Refer to curve ABD)

ASSUME: Standard time = 10 hours
Base rate = 20 cents
Efficiency = 115 per cent

$$\text{Then actual time of performance} = \frac{10.0}{1.15} = 8.70$$

hours.

10.0 — 8.7 = 1.3 hours of time saved.
Value of time saved = 1.3 × .20 = $0.26.
Bonus is one-half of this = $0.13.

WORKER'S PAY: On base rate = 8.7 × .20 = $1.74
Bonus = .13

Total pay for 8.7 hours work $1.87

$$\text{Hourly rate for job} = \frac{\$1.87}{8.7} = 21.5 \text{ cents.}$$

(B) For a point on the parabola or above 125 per cent of efficiency:

ASSUME: Standard time = 10 hours
Base rate = 20 cents
Efficiency = 165 per cent

$$\text{Then actual time of performance} = \frac{10.0}{1.65} = 6.06$$

hours.

10.0 — 6.06 = 3.94 hours of time saved.

Value of time saved = 3.94 × .20 = $0.788.

50-50 bonus is one-half of this = $0.394.

Increase in efficiency over 125 per cent = 165 — 125 = 40 per cent.

Additional bonus of one-fourth per cent of value of time saved for each per cent above 125 per cent $= \frac{40}{4}$ = 10 per cent additional = .10 × .788 = $0.079.

WORKERS' PAY: On base rate = 6.06 × .20 = $1.212
50-50 Bonus = 0.394
Differential bonus = 0.079

Total pay $1.685

$$\text{Hourly rate for job} = \frac{1.685}{6.06} = 27.8 \text{ cents.}$$

The following formula applies to the curve of the ¼ per cent principle.

New rate per hours = R
Base rate per hour = R_1
Standard time = T_1
Actual time = T_2

$$R = \frac{R_1}{4\,T_2^2}\,(T_1^2 - 0.25\,T_1\,T_2 + 3.25\,T_2^2)$$

By referring to the "per cent saving in direct labor above margin" (curve AHC) it will be noticed that the direct labor cost keeps on decreasing and the maximum saving to the company in direct labor is at 180 per cent of efficiency. The zone of the maximum saving in direct labor to the company lies between efficiencies of 165 and 195 per cent. At these points of maximum saving to the company the bonus to the worker is from 39 per cent to 64 per cent.

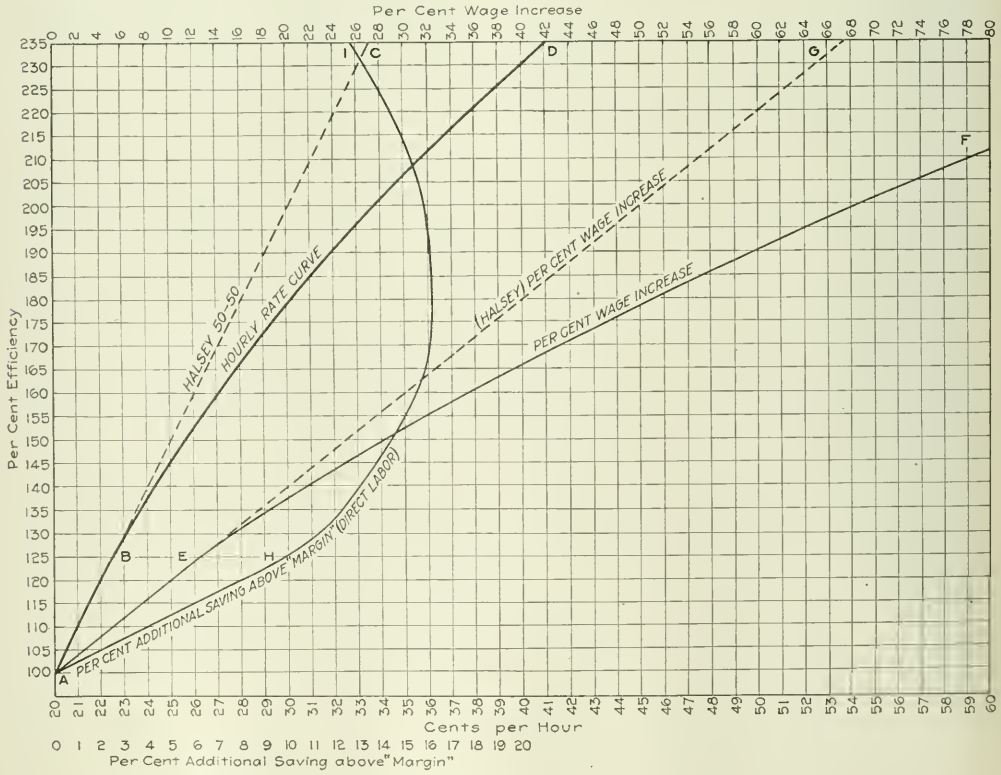

CHART II. THE BENEDICT-STRONCK DIFFERENTIAL TIME BONUS SYSTEM

Under this system, if it is assumed that a first class worker is to receive a 30 per cent extra inducement for working at his best, he would have to reach an approximate efficiency of 153 per cent.

The system under the ½ per cent principle, as illustrated by curve "DO" on the comparison chart, is identical to that of the ¼ per cent principle up to the 125 per cent efficiency point: that is,

(A) For efficiencies between 100 and 125 per cent the workers receive as a bonus ½ of the value of the time saved.

(B) For efficiencies above 125 per cent the worker receives as a bonus, in addition to half of the value of the time saved, ½ per cent of the value of the time saved for each per cent of efficiency increase above 125 per cent.

Since the relative proportion of savings given to the worker increases more rapidly under this than under the ¼ per cent principle, the worker would need only to reach an efficiency of 148 per cent to receive a 30 per cent bonus.

As will be noticed, these systems have a great flexibility of design without violating fundamental principles. The parabola may be attached to the Halsey 50-50 line at any point. The slope of the parabola may be increased or diminished by calculations other than the ¼ or ½ per cent principle, such as, a ¾ per cent or ⅓ per cent principle.

The differential feature of these systems acts as one of the most powerful of incentives. Workers strive to attain high efficiencies because their proportionate reward is so much greater. Every worker in a plant, who is industrious and fitted to his work, can earn at least some extra reward under these systems. Therefore, these systems have a strong appeal.

Application

The actual application of these systems in practice is very simple. From the curves, a table is computed which shows the per cent bonus at the various efficiencies. This per cent bonus is always a per cent of the base hourly wage.

A standard once set, under this system, need not be changed to meet fluctuations in the labor market. Every advantage of these fluctuations may be taken by fluctuating the hourly rate at which workers are engaged. This is one of the strong points of this system and, hence, has become very popular in replacing inflexible methods.

In practice a standard time, or standard output, is very carefully determined by means of motion studies, time studies, and fatigue studies, taking into consideration all economic, psychological and sociological factors entering into the problem.

Efficiency is determined in either of two ways:

$$\text{(A)}\quad \frac{\text{Standard time}}{\text{Actual time}} = \text{Efficiency per cent.}$$

$$\text{(B)}\quad \frac{\text{Actual output}}{\text{Standard output}} = \text{Efficiency per cent.}$$

By-Products

There are many very valuable by-products of these bonus systems:

(A) The standard time gives precise information as to outputs of various operations and, hence, is invaluable in determining plant capacities and the layout of scheduling methods.

(B) The standard times also give standard costs of labor which are of great value for cost accounting and estimating purposes.

(C) A direct comparison can be made of the personal effectiveness of each labor unit regardless of the kind of operation.

(D) Weak points in personnel are easily determined and brought to the attention of the proper official, so that proper remedies can be applied consisting generally of more intensive training or shifting to operations for which the worker is better adapted mentally and physically. The writer has come in contact with many cases where certain employees on the work at which they are employed could make but 60 per cent efficiency. After three or four shifts had been made to different operations, the worker was finally assigned to some operation on which he could reach from 160 to 180 per cent efficiency simply because he had ideal mental and physical qualifications for the operation selected.

Due to the flexibility of these bonus systems a far greater percentage of the workers can be placed on a reward basis than under piece work or many other plans. Practically all employees engaged in and about plants can be placed on some form of reward in proportion to their efforts expended.

Waste Elimination Bonus

In general, as production is increased the tendency is towards a decrease in quality. To overcome this, one of the strongest features is the introduction of a waste elimination bonus. These are based on identical principles as those of the production bonus; that is, a standard quality or amount of waste is set and as the quality is increased above this standard or waste decreased below this standard an extra bonus is paid. Also a very thorough training and inspection system helps greatly to increase quality. The writer has found in general that where the installation has been carefully made, quality is increased rather than diminished and in many instances there have been enormous savings in waste elimination alone.

The Design of Bonus Systems to Meet Certain Conditions

By keeping well in mind the objects to be attained and the fundamental principles involved, equitable bonus systems can be designed to meet almost any conditions.

Recently the manager of a large and prominent plant was face to face with a very serious labor problem. This plant was in a very much better condition than most plants of its kind. This executive had a far greater knowledge of the principles and practices of scientific management than the average executive. It was absolutely essential that production be considerably increased. Due to the extreme scarcity of labor the best possible method for increasing the production was by increasing the effectiveness of the present labor forces. It was realized that the strongest possible method would be the introduction of some incentive form of wage payment. The entire plant had

been on a day work basis since its conception. The attitude of the employees had always been strongly against anything but day work and the chief problem was to submit to them some form of wage payment plan which would be acceptable to them and to which they would give their full and hearty co-operation. After a thorough study of the conditions, in all their various phases, the writer designed and introduced a bonus system which met with the hearty approval of the employees. As a result, the average production of such operations on which the method has been applied to date has increased approximately 65 per cent. The average wage to employees under the bonus plan has been increased from 25 to 30 per cent. The object has been attained. The management profited by the tremendous increase in production and the decrease in labor costs and the employees by a considerable increase in their earnings.

Actual practice has shown that the differential time bonus system is far superior to piece work. A certain plant had been on piece work for years. On analyzing the operations it was found that the evil of limitation of output existed. The piece work system was replaced by a differential time bonus system and a very marked increase in production was effected throughout this plant.

Determination of Standards

The success of any payment plan of this kind rests upon the accuracy and equitableness of the standard times. By applying modern methods of motion and time study and a thorough study of the fatigue problem equitable standards can be set. Such standards, however, should not be set by untrained persons but under the guidance of experts, thoroughly familiar with analysis, fatigue, and such economic, psychological and sociological factors as have a bearing on the attitude of labor.

Working Hours

In most industries, the tendency now appears to be toward the eight-hour day. Statements have been made at various times that the same output could be obtained by reducing from a ten-hour to an eight-hour basis. These statements may have been true in certain cases, but in general this is not the case. Any given plant, however, operating under a ten-hour basis under day work or a wrong wage payment plan can be made to produce as much, and even more, in eight hours than in ten hours by a more thorough analysis and standardization of operations, better training of workers, improved scheduling methods, and the introduction of the best possible type of bonus system.

In many industrial districts, especially in such plants working on war supply contracts, the eight-hour day is in effect, but in the majority of cases the workers actually are employed ten hours and receive time and one-half for overtime over eight hours. This appears to be the popular trend today.

The Dilution of Male Labor with Female Labor

Owing to the great scarcity of labor it has become absolutely essential to employ women in industry. In order to be successful in this undertaking, far better methods of all kinds must be applied. The problem of intensive training and supervision becomes greater. There are numerous operations in almost every plant which can be performed by women and by proper selection, training, and supervision and by improving working conditions, in the course of time the outputs on such operations will be just as great, if not greater, than under former male labor.

Conclusion

In conclusion, it must be stated that even the best and most approved wage payment plan is not a cure for all ailments. It is absolutely essential, and a patriotic duty to every industrial organization to see that the greatest possible production with the least waste and cost is obtained. An ideal bonus system may have no effect whatsoever, or a disastrous effect, in case it is wrongly applied. Owing to the tremendous importance of the problem and the effect of such methods, it is the duty of every executive contemplating the introduction of such plans to see that:

(A) The design of the method is absolutely correct and does not violate fundamental principles.

(B) That the plan be correctly introduced.

Where this is done the objects will be attained and the results will be to the ultimate benefit of both employer and employee, which is the acid test of any method or plan.

Chicago, Ill.

Foreign Trade Convention Postponed.—The Executive Committee of the National Foreign Trade Council announces that "owing to the railroad congestion and the desire of the council to co-operate with the Government in the relief of the situation due to the war," the dates of the Fifth National Foreign Trade Convention to be held at Cincinnati, Ohio, have been changed from Feb. 7, 8 and 9 to April 18, 19 and 20, 1918. Merchants and manufacturers who are desirous of receiving invitations to attend the convention at Cincinnati are requested to send their names and addresses to O. K. Davis, Secretary National Foreign Trade Council, 1 Hanover Square, New York City.

Tariff Committee of Dyestuffs Association.—The Committee on Organization has appointed the following Tariff Committee: Dr. J. Merritt Matthews, chairman; August Merz of Heller & Merz; R. T. Dicks of Dicks, David & Co., and H. G. McKerrow of E. F. Drew & Co., all of New York; L. A. Ault of Ault & Wiborg Company of Cincinnati, and C. S. Althouse of the Althouse Chemical Company of Reading, Pa. The committee held a meeting on Feb. 11, at which the final proposals to be submitted to the Tariff Commission were gone over. It will hold another session in Washington immediately before conferring with the Commission. This committee has formulated definite ideas as to what the tariff regulations should be in order to safeguard the industry and has also determined upon what is considered a just and fair schedule of tariff rates. These are being withheld for the present by the committee, pending two conferences which that body has arranged to hold with the United States Tariff Commission in Washington.

It is expected that this committee's report will be in such shape that it may be included in the report of the main committee to the meeting of the main body of the newly organized association on March 6 at the Chemists' Club in this city.

The Vulcanization of Rubber

By ANDREW H. KING

THE whole structure of rubber products rests upon one important discovery—vulcanization. In 1839 Goodyear of New Haven, Conn., found that rubber, when mixed with sulphur and heated, underwent a "change." That is, that its physical properties were decidedly altered. It now had a much greater stability toward temperature changes, and showed a large increase in tensile strength and elasticity. This was the principal and basic discovery, and is used in nearly all the rubber shops the world over. The cold process of vulcanization by the use of a dilute solution of sulphur chloride, S_2Cl_2, was developed by Alexander Parkes in 1846. There is no question as to the relative importance of the two discoveries. The cold process finds application only with extremely thin pieces of rubber, such as toy balloons, etc., and some kinds of spread goods.

Regardless of the manner in which it comes about, vulcanization is similar to the hardening or coagulation of a gel. A typical example of such a change is the behavior of glue with tannin. It requires no great stretch of the imagination to compare it with the setting of a custard pie or the baking of a fruit cake. The fruit cake idea is of particular value in that it gives us a simple homely parallel which will serve to make the mystery of compounding and vulcanization a little more understandable.

In preparing a cake the first concern of the cook is to produce a colloidal suspension, a batter consisting of milk, flour and eggs. To this are added the sugar, fruit, flavoring, baking powder, etc. When completed it is in the form of a not too stiff dough. It is then poured into pans and baked. The heat sets or coagulates the gel. That it happens also to liberate a gas which brings about porosity does not alter the similarity. In fact, in preparing sponge rubber the rubber chemist also resorts to this trick. The pastry cook must understand the preparation of the gel. He must know how to produce the properties of taste, flavor, etc., which make a cake so desirable to mankind. Compounding is not greatly different. It is the art of mixing various materials with rubber which give to it, subsequent to vulcanization, certain desirable physical properties.

The first step in the preparation of a stock is to break down the rubber. This is accomplished on a mill which consists essentially of two large horizontal rolls which rotate toward one another. To break down the rubber is, as is implied, to render it soft and plastic like a dough. When this condition is reached the various compounding ingredients are added. The plastic rubber takes them up in much the same way as bread dough takes up more flour. The rubber behaves as a super-cooled liquid and a stock is no more nor less than a solid solution. That the solid fillers are not added in lumps like chopped fruit to a cake but in very fine powders is due only to the fact that more desirable physical properties are obtained thereby. The unvulcanized stock is a highly plastic mass with but very little elasticity or strength. Vulcanization reverses the situation, after which we find it strong and elastic with but very little of the original plasticity remaining. The effect of the individual fillers will be discussed in a later paper, but it will suffice here to say that their general effect is to decrease the stretch and to increase the tensile strength, hardness, toughness, and resistance of the stock to wear. This effect is not in direct proportion to the volumes involved, for some fillers give a greater increase and some a less. For example, if equal volumes of gas black and barytes be added to rubber in two separate but otherwise similar batches, the one containing the black will show a higher tensile strength and a relatively lower stretch, while that containing the barytes will show a lower strength and a higher stretch. This difference in behavior may be due to a number of things but is thought to be fundamentally a phenomenon of adsorption.

The above gives a general idea of the usefulness of vulcanization. We will now go on the various theories which have been advanced from time to time, as explanations of the mechanism by which it occurs. These theories are all of them incomplete and imperfect. But poor as they are they afford us a vehicle of thought and their proof or disproof advances our knowledge of the subject.

Chemical Theory

Carl Otto Weber was the first to investigate the chemistry of vulcanization. He divided the sulphur of a mixing, subsequent to heating, into two classes—free and combined. The first was removable by solvents, acetone being most satisfactory. The second, combined sulphur, he was never able to eliminate. In fact, no one with the possible exception of Spence, has ever been able to do it either. He found that rubber containing less than 2 to 2½ per cent combined sulphur did not show completely the physical characteristics of a properly vulcanized stock. First evidence of the "change" is seen when the combined sulphur is about 1.25 per cent. The physical properties become better and better until 2 to 2½ per cent combined sulphur is reached. He therefore concluded that this amount of combined sulphur was necessary to produce the first of a series of compounds which he called polyprene sulphides, the empirical formula of which he thought to be $(C_{10}H_{16})_{10}S$ which indicates 2.3 per cent combined sulphur. By using larger amounts of sulphur and a longer period of heating he obtained, just as did Goodyear before him, a hard substance, an ebonite, which contained approximately 32 per cent of combined sulphur. Try as he might he was unable to produce an ebonite with more than this amount of combined sulphur. This would indicate a compound of the formula $C_{10}H_{16}S_3$ or better $C_{100}H_{160}S_{30}$, which he concluded to be the highest member of his series of polyprene sulphides. As evidence which would tend to prove the existence of the intermediate members of the series, he recorded that the relation of combined sulphur to time, tempera-

ture being held constant, was not a linear function but that certain breaks were noticeable in the curve. Each break he thought indicated a new polyprene sulphide. Axelrod thought somewhat differently of the matter. He considered, and rightly, that heat has two effects on rubber, first to make it soft, plastic and tacky, to depolymerize it; and second to bring about the combination with sulphur. The breaks in the curve he concluded showed depolymerization, followed by further addition of sulphur. He did not seek to overthrow Weber's theory but only to supplement it. Now it happened that Weber heated mixtures of sulphur and rubber (9.1 per cent sulphur) in an autoclave at fixed temperatures between 120 deg. C. and 130 deg. C. Samples were withdrawn every hour or half hour and their combined sulphur determined. It is not surprising in view of such faulty technique that the curve contained several sharp bends. Every time the autoclave was opened to remove one piece the other pieces were undoubtedly cooled off. No one has ever isolated these intermediate polyprene sulphides, which fact gave Wolfgang Ostwald a point in favor of the adsorption theory. The investigation was at a standstill for a number of years until Spence, seeking to prove the adsorption theory, heated different samples of a mixture of rubber with 37 per cent sulphur for varying lengths of time. His combined sulphur curve showed a regular increase with time from zero up to 31.97 per cent. There were no breaks nor bends in his curve whatever. He did show, however, that the removal of the free sulphur gave typical adsorption phenomena and concluded that the first step of vulcanization is adsorption of the sulphur, after which a part of it becomes chemically combined.

The evidence in favor of the chemical theory may be summarized as follows:

1. There is no process by which the combined sulphur can be removed and the original rubber regenerated. Reclaiming processes remove only the free sulphur.

A possible exception to this statement may be found in a late patent to Spence (U. S. 1,235,850) in which he claims to actually devulcanize rubber. After the removal of the free sulphur the combined sulphur is eliminated by heating in an aniline solution of metallic potassium or sodium for several hours at 175° C. The solution is filtered, the aniline distilled off and the rubber dissolved in benzol, when it is purified by treatment with water containing hydrochloric acid. Piperidine, caustic soda, and para aminodimethyl aniline, all powerful vulcanization accelerators, are recommended to assist and to speed up the devulcanization. Seventy-three per cent of the combined sulphur in ebonite was removed in one operation. The principle of the process is simple. Spence reasoned that all that was necessary was a powerful vulcanization accelerator in conjunction with an element capable of combining with and fixing the sulphur liberated from the rubber by the accelerator. The more powerful the accelerator the more rapid would be the devulcanization. It is to be sincerely hoped that Spence will be entirely successful in his experiments, and that their commercial application will not be long delayed. A reclaiming process which will truly devulcanize rubber is sorely needed. But should this process be successful it will not in the least invalidate the chemical theory, but will rather strengthen it, showing merely that another reaction takes place during which another substance combines with and removes the sulphur from the rubber. That such substances are powerful accelerators throws considerable light on the mechanism of acceleration, which will be discussed later.

2. Alexander showed that there was a definite stoichiometric relation between the maximum quantities of sulphur and bromine which may be added on. For instance, the maximum quantity of bromine which may be added is equivalent to 32 per cent of sulphur. Also, if 16 per cent of sulphur is already combined with the rubber the maximum amount of bromine which may be added is equivalent to 16 per cent of sulphur. Ebonite with 32 per cent combined sulphur cannot add on any bromine. You will note that we are here speaking of addition in the sense that it is known to the organic chemist and which differs considerably from substitution. The addition of bromine to rubber is considered by most chemists as taking place at the double bonds. It is not unreasonable then that sulphur should combine in the same way.

3. Vulcanization is subject to conditions like any other chemical reaction. Increased temperature accelerates it. The mass action effect of sulphur is marked and the catalytic behavior of certain substances is well known.

4. The work of Hinrichsen has shown that cold vulcanization by means of sulphur chloride is a true chemical reaction. The maximum quantity of sulphur chloride which may be added is about 33 per cent S_2Cl_2 which would indicate a compound $(C_{10}H_{16})_2S_2Cl_2$.

Vulcanization, according to the chemical theory, must be due to the chemical combination of sulphur with rubber, which combination probably takes place at the double bonds and is an addition and not a substitution. The existence of but one polyprene sulphide has been definitely established, namely, ebonite $(C_{10}H_{16})S_2$.

Adsorption Theory

This theory was advanced by Wolfgang Ostwald some years ago. He considered vulcanization to be simply a case of physico-chemical adsorption. The main points in support of his theory are:

1. Some free sulphur always remains after vulcanization. This fact Ostwald considers an evidence of adsorption on the ground that if vulcanization were a chemical reaction there should be certain conditions under which no free sulphur would remain. It is axiomatic that for any chemical reaction to go to completion the product of the reaction should be removed as fast as formed. This is obviously impossible in this case. The colloidal nature of rubber also tends to retard the reaction and prevents its completion.

2. Ostwald based another claim on the bends in Weber's curve. He pointed out that the different polyprene sulphides had never been isolated and that their existence might be explained equally well by the adsorption theory. In view of Spence's work the question requires no further comment.

3. Sulphur may be removed by suitable solvents on long treatment. This statement has been disproved many times. Spence has shown that the free sulphur

may be removed and that it is truly adsorbed. Combined sulphur is insoluble.

4. Figuring from Weber's data Ostwald obtained 1.87 for the temperature coefficient. Van't Hoff calculated that for a chemical reaction between rubber and sulphur a coefficient of 2 to 3.5 would be required. Adsorption gives a coefficient of 1.36 and while 1.87 is certainly nearer to 2 than 1.36, yet Ostwald held this to be in favor of his theory. The temperature coefficient based on Spence's work is 2.65.

5. Stern dissolved rubber and sulphur in fused naphthalene. His results were not satisfactory but he concluded that they were more in accord with the adsorption theory than with the chemical theory. It might be observed that rubber when dissolved in any solvent and heated, becomes rapidly depolymerized and if the operation is continued for any length of time it loses its normal properties and becomes more and more like the terpenes.

There is to date no evidence that a chemical reaction does not take place and the adsorption theory, as a theory to stand alone, has been definitely disproved.

Ostromyslenski's Theory

This theory came about through a study of the addition products of rubber with various aromatic compounds. Ostromyslenski found that substances which ordinarily form addition products such as picric acid, picryl chloride, triphenyl methane, etc., did not produce vulcanization but that compounds rich in oxygen such as nitro-compounds capable of giving up some of it did produce the "change." This led him to try benzoyl peroxide which readily yields oxygen, and it also vulcanized. He obtained best results with 1:3:5 trinitrobenzol and benzoyl peroxide, $C_6H_5—CO—O_2—CO—C_6H_5$. Physical tests on rubbers vulcanized according to his directions were made by Stevens' and are given in Tables I and II. The value of his work has been questioned on the ground that his "vulcanized" products were inferior to rubber vulcanized by sulphur. This is true, all but benzoyl peroxide and trinitrobenzol give hopelessly low results, and these while better than the rest, do not produce a vulcanized product equal to that of sulphur. However, he did obtain the "change" and his products were in most cases superior to the original crude rubber.

Because of the fact that substances with such widely different chemical and physical properties as the peroxides, nitro-compounds, sulphur and sulphur chloride, all produce vulcanization it is probable that vulcanized rubber as we know it is not the product of a simple chemical reaction, but that the vulcanizing substance first acts chemically on a small portion of the rubber forming a derivative which is in turn adsorbed by the unchanged rubber.

He further supported his theory by obtaining vulcanized products with rubber bromide and hydrochloride.

His theory is then, that only on polyprene sulphide, $C_{10}H_{16}S_2$ is formed, and that this substance being adsorbed on the remaining rubber gives it the properties which lead us to call it vulcanized. Thus he combined both the chemical and adsorption theories. No one has yet, to my knowledge, produced vulcanized rubber by heating caoutchouc with polyprene sulphide. This may

not be an objection because of the difficulties of obtaining $C_{10}H_{16}S_2$ in a condition in which it may be readily adsorbed. Before the theory can be accepted some one must find a solvent for or a method by which polyprene sulphide may be separated from the unchanged rubber. Should this be done, and it may be accomplished, it would not be the first time that the product of a chemical reaction adsorbed on the unchanged substance in varying amounts, gave rise to a belief in a whole series of compounds where only two actually existed. A classic example of this statement is found in the confusion in the past regarding the oxy-celluloses.

Erdmann's Theory

The friends of both the chemical and Ostromyslenski theories consider that a true chemical reaction takes place between rubber and sulphur. The Erdmann theory is of importance because it seeks to explain the mechanism of this reaction. At 160° C., which is practically the upper limit of vulcanizing temperatures, molten sulphur contains a large portion of thiozone molecules, S-S-S. It is considered that thiozone acts on rubber in the same manner as ozone producing a thiozonide of caoutchouc.

The theory is of particular interest in that it gives us a partial explanation of the behavior of organic accelerators. Ostromyslenski has produced some evidence that these catalysts are substances which are capable of forming thiozonides with sulphur. If this is true it is quite probable that vulcanization proceeds in the following consecutive steps:

1. The union of the accelerator with sulphur forming a thiozonide. No accelerator has yet been found which does not contain nitrogen. The junction likely occurs between the nitrogen and sulphur atoms.

2. The addition of the thiozonide to the rubber molecule.

3. The splitting off of the accelerator, leaving the sulphur attached to the rubber. We cannot be sure that this splitting off always occurs. In fact, there is an indication in the peculiar snap and altered physical properties of stocks vulcanized by the aid of hexamethylenetetramine, which makes it seem probable that the thiozonide of this accelerator does not split off the catalyst after combining with the rubber.

The point has been raised by Eaton that accelerators are not true catalyzers because they do not remain unchanged throughout the reaction. It is quite true, so far as we know, that no accelerator remains absolutely unchanged during vulcanization. But there is yet no evidence which would tend to indicate that the accelerator is not split off from the rubber in the unchanged condition and that the decomposition is not brought about by side reactions. For example, the odor of phenyl mustard oil is always noticeable about a thiocarbanilide stock when it is freshly removed from the vulcanizing press. Thiocarbanilide when heated under several conditions sets free phenyl mustard oil. There is no evidence to show that the decomposition of thiocarbanilide producing phenyl mustard oil during vulcanization is not a secondary reaction. Phenyl mustard oil $C_6H_5.N = C = S$ has comparatively little accelerating value.

Relation Between Coefficient of Vulcanization and Physical Properties.

This subject is one which has aroused rather severe controversies across the water during the past couple of years. In fact it is as yet unsettled. The term coefficient of vulcanization was introduced by Weber and means simply the percentage of combined sulphur based on the rubber. It is admitted by all concerned that a correctly vulcanized rubber gives more general satisfaction than one which has not the correct degree of cure. The point at issue is, What is the correct cure and how may it be recognized? The coefficient of vulcanization is certainly indicative but its use is restricted because very few rubbers are polymerized to the same degree. It is also limited by the difficulties surrounding a correct determination of combined sulphur since the universal method is to extract the free sulphur and determine the combined sulphur by difference. There is no method for determining the combined sulphur directly. The free sulphur, as has been already pointed out, is adsorbed. Its complete extraction within reasonable time is impossible. Consequently purity of solvent, kind of solvent, dimensions of extractor, time of extraction, condition of the rubber, etc., must all be rigidly defined before chemists may use the coefficient as a basis. After its determination is reduced to a working basis it is still of questionable value unless sulphides are determined. We look on rubber as having the empirical formula $(C_{10}H_{16})_n$, n being a variable. When it is low, as is the case for rubbers of low natural polymerization or for those which have been overworked on the mills, more sulphur combines on vulcanization than is the case for rubbers of high natural polymerization, as for example, fine Para. In other words, the coefficient of vulcanization is higher in the first mentioned cases. I do not wish to leave the impression that good rubber may be overworked on the mills and by the simple expedient of adding on more sulphur attain the properties of a correctly milled stock. Overmilling is always detrimental.

De Vries[2] has put the proposition well:

"From my experiments it is clear that the reaction between sulphur and rubber and the changes in the rubber-sulphur mixture which determine the mechanical properties as expressed in the stress-strain curve are two different processes which proceed independently of one another and that speaking in general it is not feasible to make deductions from one regarding the other."

The compounder has only a passive interest in the coefficient of vulcanization. He is entirely wrapped up in the physical properties of his stocks. The coefficient may be 2 or 6 provided his compound meets specifications. He realizes, of course, that he must always obtain the correct cure but he prefers to judge this point from the physical properties rather than by the coefficient of vulcanization. He bases his judgment on such considerations as tensile strength, stretch, set, the characteristics of the stress-strain curve, and on an indefinite something which he calls "feel" but which is really the summarization of his experience with the particular type of stock in question.

Production and Rate of Cure.

Vulcanization is essentially a chemical reaction. This statement is one in which every rubber chemist will concur. The rate of cure is susceptible to the same influences as effect the speed of a chemical reaction. The most important considerations are:

1. Mass action.
2. Catalysis.
3. Temperature.

MASS ACTION

As would be expected, an increase in sulphur content decreases time required for vulcanization. The mass action effect has been investigated by Skellon.[3] He reports the following figures:

	Added Sulphur						
Time of Cure	3%	5%	10%	20%	30%	40%	50%
	Combined Sulphur						
30 min. @ 140° C.	.36	.44	.63	.59	.55	.51	.48
1 hr. @ 140° C	.46	.63	1.07	1.05	.95	.83	.76
1 hr. 30 min. @ 140° C	.70	1.02	1.65	1.64	1.47	1.32	1.15
3 hrs. @ 140° C	1.42	2.06	3.35	4.07	3.58	3.13	2.81
6 hrs. @ 140° C	.	2.88	6.18	11.33	11.62	10.93	10.22
9 hrs. @ 140° C	.	.	8.76	17.32	24.10	25.5	25.0

CATALYSIS

Whether we choose to call it catalysis or acceleration, its effects are to be seen in the behavior of every mix on vulcanizing. Some substances speed up the reaction while others retard it. The chief retarders or negative accelerators are:

1. Alkali in excess of 3 per cent.
2. Acids.
3. Molybdenum sesquioxide over 10 per cent.
4. Nickel oxide.
5. Phenylhydrazine.
6. Glucose.
7. Methylene blue.
8. Most oils and greases.
9. Asphaltic products.

Some of these are not true negative catalyzers but mere sulphur removers in that they react with sulphur as easily or easier than rubber.

In a previous paper[4] the writer gave a partial review of the organic accelerators. To this list may now be added:

[2] *I. R. J.*, Jan. 20, 1917, p. 17.

[3] Rubber Industry, 1914.

[4] This journal, Sept. 1, 1916, p. 231.

1. Para Nitroso-Dimethyl Aniline.

Nitroso derivatives of methyl aniline, dimethyl aniline, ethyl aniline and diphenylamine are powerful accelerators.[3] P-Nitroso-dimethyl aniline, sold under the trade name of accellerene, is the best. It is a green crystalline powder melting at 85 deg. Cent. and is produced by the action of nitrous acid on dimethyl aniline. The structural formula is

Peachy states that the addition of .3 to .5 parts accellerene to a mix of 100 parts rubber, 10 parts sulphur, cuts the time from 1 hour at 140 deg. Cent. to 20 to 25 min. at the same temperature. This mix probably contained, though not stated, some mineral accelerator such as lime or magnesia. With hard rubber the addition of 0.75 per cent accelerene to a mix of 100 parts rubber, 40 parts sulphur cuts the time from 6 hr. at 140 deg. Cent. to 2 hr. In general the addition of .3 to .5 parts of P-Nitroso-dimethyl aniline to high quality stocks cuts the time to 1/3 or 1/4 that formerly required. It cannot be used with antimony sulphide, litharge, or shoddy. The addition of magnesia is a decided help.

2. Condensations between aldehydes and amines.

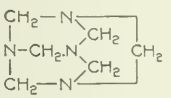
Type reaction: Benzaldehyde with aniline forming benzylidene aniline.

$$C_6H_5CHO + H_2NC_6H_5 = H_2O + C_6H_5.CH:N\,C_6H$$

This is an active accelerator but less so than P-Nitroso-dimethyl aniline.

3. Hexamethylene tetramine:

This substance $(CH_2)_6N_4$ is produced by the action of ammonia on formaldehyde at ordinary temperatures. It is a crystalline basic substance having the structural formula:



This accelerator must not be used in conjunction with litharge, magnesia, or lime. About the only metallic oxide with which it is not incompatible is zinc oxide. It is about twice as powerful as thiocarbanilide, and must be used in rather small amounts. It gives a stock a peculiar snap and stiffness unlike any other accelerator known.

4. Piperidine-piperidyl-dithio-carbaminate:

This accelerator is by far the most powerful of all those known to-day. First mention of it was made by Ostromyslenski[4]. It is formed by the action of carbon bisulphide on piperidine.

$$2(CH_2)_5NH + CS_2 = [(CH_2)_5NH]_2CS_2$$

The reaction is similar to that producing thiocarbanilide from aniline and carbon bisulphide except that no hydrogen sulphide is evolved.

Thiocarbanilide

The addition of .5 to 1 per cent in conjunction with 5 per cent magnesia or litharge diminishes the time required for vulcanization to 1/40th of the original time. In the presence of 2 to 5 per cent of the accelerator, vulcanization of either synthetic or natural rubber is complete in a few seconds at 130 deg. Cent. Stocks containing it to the extent of 2 per cent will become fully vulcanized on standing at room temperature for a month. Unfortunately it is far too powerful and too expensive for factory practice.

Accelerators in more ways than one are similar to explosives. Properly used they are a boon, but used without discretion they can produce more havoc on a firm's balance sheet than anything I know of. To get results one must have long experience with them and must take nothing for granted. In general, a combination with one or more of the metallic oxides works well, but this must be very carefully studied before final decision.

TEMPERATURE

As stated previously, vulcanization is essentially a chemical reaction brought about by heat. In common with such reactions the application of a higher temperature brings it to completion in a shorter time. It was formerly held that high temperatures were harmful, and so they are when the nature of the article is such that heat flow is very slow, but whenever the piece can be brought to press temperature through and through in a very short time, a higher temperature for a shorter time produces a better article than a lower one for a longer time. The subject has been investigated by Kratz[7], who reports the following figures on a stock made up of 100 parts first latex crepe, 100 parts zinc oxide, and 5 parts sulfur.

Time, Min.	Steam Pressure, Lb. Sq. In.	Temperature, °F.	Tensile Strength, Lb./Sq. In.	Stretch, per Cent	Tensile Product
120	36	282	2896	750	217
90	43	290	2747	725	200
60	50	298	2755	725	200
43	55	303	3064	725	222
30	60	307	2947	775	229
22	65	312	2854	800	228
18	70	316	2563	750	193
14	75	320	2656	725	192
11	80	324	2545	750	191
8	85	328	2970	800	238

The relation between temperature and rate of vulcanization has been investigated by Bourn[8], who has summarized his experiments in the following statements:

1. The velocity of the combination increases faster than the increase of temperature, and decreases correspondingly with a decrease of temperature.

2. For every increase in temperature of about 11 deg. Fahr. the velocity is doubled, and for each decrease in temperature of about 11 deg. Fahr. the time required is doubled.

3. Above 304 deg. Fahr., when the constitution of sulfur changes, the velocity doubles in approximately 25 deg. Fahr. instead of 11 deg. Fahr.

PRODUCTION.

The novice might imagine that if one can use accelerators and reduce the time required for vulcanization from 1 hr. to 25 min. that the desirable thing to do would be to put in more accelerators and pull the time down to 5 min. or to zero time for that matter. That line of reasoning would be correct provided no condi-

[3]British Pat. 4263, 1914. Peachy, I. R. J., May 12 and 19, 1917

[7]I. R. J., 1916, p. 661
[8]Rubber Industry, 1914.

tions other than production had to be met. Unfortunately there are other factors to consider. Chief of these are:

1. Stages in factory process.
2. Heat conductivity.
3. Stocks in contact.

STAGES IN FACTORY PROCESS

These include milling, calendering, tubing, etc., regular factory operations during which there must be no scorching. By scorching I mean the partial vulcanization brought about by overheating. This tends to give lumpy stocks unsuitable for further operations. A stock must not be too heat-sensitive.

HEAT CONDUCTIVITY

Rubber is not a good conductor of heat. Small articles, such as the average piece of molded goods, heat up quickly, but large bulky articles require an appreciable time for the heat to penetrate into the interior. Built-up articles such as hose, belting, etc., containing cotton duck do not permit a rapid flow of heat to the interior and must be cured at comparatively low steam pressure, 30 lb. or under; the idea being to prevent the outside layers from becoming over-vulcanized while the interior would be yet under-cured.

A low temperature requires a long period of heating and reduces production. The usual manner of circumventing this difficulty is to use a "rising cure." A typical example of such a cure is as follows:

20	min.	@	20	lb.	steam	pressure
30	"	@	30	"	"	"
40	"	@	40	"	"	"

As the name implies, the heat is increased in successive steps which are made far enough apart to allow complete penetration and equalization before going on with the next step.

STOCKS IN CONTACT

Under this head we must consider not only such stocks as may be in actual contact but all the stocks which enter into the makeup of the article. For example, in the pneumatic tire we have different stocks for the tread, cover, cushion, breaker strip, sidewall and bead. The compounder must so adjust his stocks that all of them will reach the desired degree of vulcanization at the end of the period. Most beads are semi-hard rubbers and must be partly cured before being built into the tire. In general, stocks in contact should have the same rate of cure.

A New Source of Potash

Present Development and Future Possibilities of Extraction from Chile Nitrate

A SOURCE of potash which has not been seriously considered heretofore, and which has enormous possibilities, was described by C. M. Barton, vice-president of the du Pont Nitrate Company, at a recent meeting of the Delaware Section of the American Chemical Society in Wilmington. He stated that not only had the du Pont Company succeeded in producing potash in paying commercial quantities from the Chilean nitrate ores, but that it had given its processes to the representatives of companies from allied and neutral countries which operate plants in the nitrate fields of Chile.

The du Pont Company produces only about one per cent of the output of the Chilean nitrate fields, but it has succeeded, by its processes, in producing 10,000 tons a year of a product containing 25 per cent of potassium nitrate. This is equivalent to about 1200 tons of potassium oxide.

The others of the 200 nitrate plants in Chile are capable of producing an average quantity of potash equal to that produced by the du Pont Company. On this basis the production would be 240,000 tons a year, but the process can be further developed and improved. There is good reason to believe that in a short time it can be improved to such an extent that instead of recovering about one-third of the potash in the ore it may be possible to recover virtually all and thereby bring the total possible output up to 720,000 tons a year. This is almost as much as the entire pre-war consumption of potash in the United States.

Germany's sale of potash before the war to the entire world amounted only to about 900,000 tons a year.

Mr. Barton outlined the process during his talk and stated that this process had been in operation and had been improving constantly for a long while. He said:

> "From the beginning of our operations we had known that our caliche at Oficina "Delaware" contained some potash and that our product contained on an average about 5 per cent of nitrate of potash. Working constantly on various theories for securing better yields and knowing that we could secure a desirable product for our refineries if we could get a nitrate containing a higher percentage of nitrate of potash, we found that by taking the mother liquor coming back from the crystallizing pans and evaporating it to a high density there was deposited from this upon cooling a product which contained on an average about 25 per cent of nitrate of potash. We had not found it a practical proposition to install evaporators for this purpose until in the latter part of the year 1914, when the price of muriate of potash started to climb up from $35 per ton to a peak price of about $500 per ton. In October, 1914, we produced our first H. P.—or high potash nitrate—and by securing further evaporators were able to increase our production of this, so that we have for a year or more secured about 25 per cent of our output in this form. We estimate roughly that up to October, 1917, we secured from this source at least 5000 tons of nitrate of potash, in the form of about 20,000 tons of our so-called 25 per cent H. P. nitrate.
>
> "We erected three evaporators near the end of the maquina. The first was an old evaporator which had formed a part of the old Nordenflycht maquina, which was on the property when we bought it. The old maquina was torn down and parts of this old evaporator had been utilized for other purposes, but were reassembled, and it has been giving steady use. The other two evaporators we bought from another nitrate company that had received but never erected them, owing, we believe, to their having gotten 'cold feet' due to the trouble others had experienced through corrosion in evaporators when treating the liquors of the usual operations. We anticipated the corrosive effects, suffered from them, but a year ago were able to eliminate or at least minimize the corrosion very effectively by the addition to the liquor of a small amount of sodium carbonate.
>
> "You can understand that this H. P. nitrate has proven very valuable to the du Pont Company, and we kept rather quiet about this portion of our operations until shortly after our entry into the war. It was then realized that the needs of the country were such that it was to the interest of the du Pont Company to surrender its position of vantage, and the representatives of the allied and neutral governments, whose subjects operate nitrate plants in Chile, were advised that the du Pont Company was willing to share with them its secrets in the production of this material."

The value of this process is emphasized by the fact that potash produced in Chile is a by-product of the nitrate industry, and hence can be produced very cheaply.

The Effect of Addition Agents in Flotation—III.

By M. H. THORNBERRY and H. T. MANN

As in the preceding discussion of the effect of addition agents in flotation, the results obtained by the addition of various chlorides are shown graphically in Charts 10, 11 and 12. The numerals on the charts are the numbers of the various experiments, three being made without any additions and four with each of the different agents. Those without addition agents are numbered 1, 2, 3 and 0, the last showing the average results of the first three. The numbers of experiments with addition agents are given in the following paragraphs, four to each experiment, and indicate results obtained respectively with 5, 15, 25 and 50 cc. of each agent.

To save repetition in the discussion of the results we shall refer in this article to Cleveland Cliffs Iron Company's flotation oil No. 1, as "oil No. 1," and to General Naval Stores flotation oil No. 17, as "oil No. 17."

The reader should also bear in mind that when statements are made that a certain reagent raised or lowered the grade of concentrate or extraction, those results are compared with the results obtained when oil was used without any reagent.

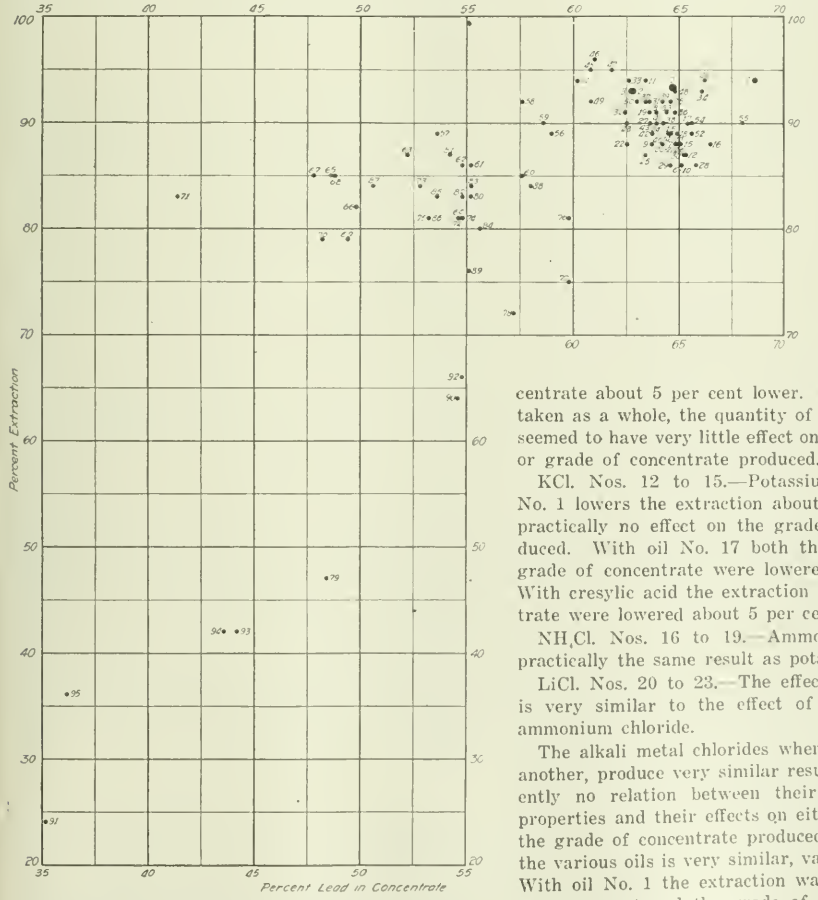

CHART 10. ADDITION AGENTS IN FLOTATION. EFFECT OF CHLORIDES ON THE FLOTATION OF GALENA WITH CLEVELAND CLIFFS IRON CO.'S OIL NO. 1

CHLORIDES

Alkali Metal Chlorides

NaCl. Nos. 8 to 11.—Sodium chloride when used with oil No. 1 had very little effect. The average extraction was about 4 per cent lower, while the grade of concentrate was practically of the same grade as when no reagent was present. With oil No. 17 the extraction was lowered 9 per cent to 10 per cent, and the lead tenor of the concentrate was about 9 per cent lower. With cresylic acid the extraction was about 6 per cent lower and the concentrate about 5 per cent lower. When the results are taken as a whole, the quantity of sodium chloride used seemed to have very little effect on either the extraction or grade of concentrate produced.

KCl. Nos. 12 to 15.—Potassium chloride with oil No. 1 lowers the extraction about 5 per cent, but had practically no effect on the grade of concentrate produced. With oil No. 17 both the extraction and the grade of concentrate were lowered about 10 per cent. With cresylic acid the extraction and grade of concentrate were lowered about 5 per cent.

NH_4Cl. Nos. 16 to 19.—Ammonium chloride gives practically the same result as potassium chloride.

LiCl. Nos. 20 to 23.—The effect of lithium chloride is very similar to the effect of both potassium and ammonium chloride.

The alkali metal chlorides when compared, one with another, produce very similar results. There is apparently no relation between their individual chemical properties and their effects on either the extraction or the grade of concentrate produced. Their action with the various oils is very similar, varying only in degree. With oil No. 1 the extraction was lowered 4 per cent to 5 per cent and the grade of concentrate produced averages less than 1 per cent low. With oil No. 17 the extraction was lowered about 12 per cent and the grade

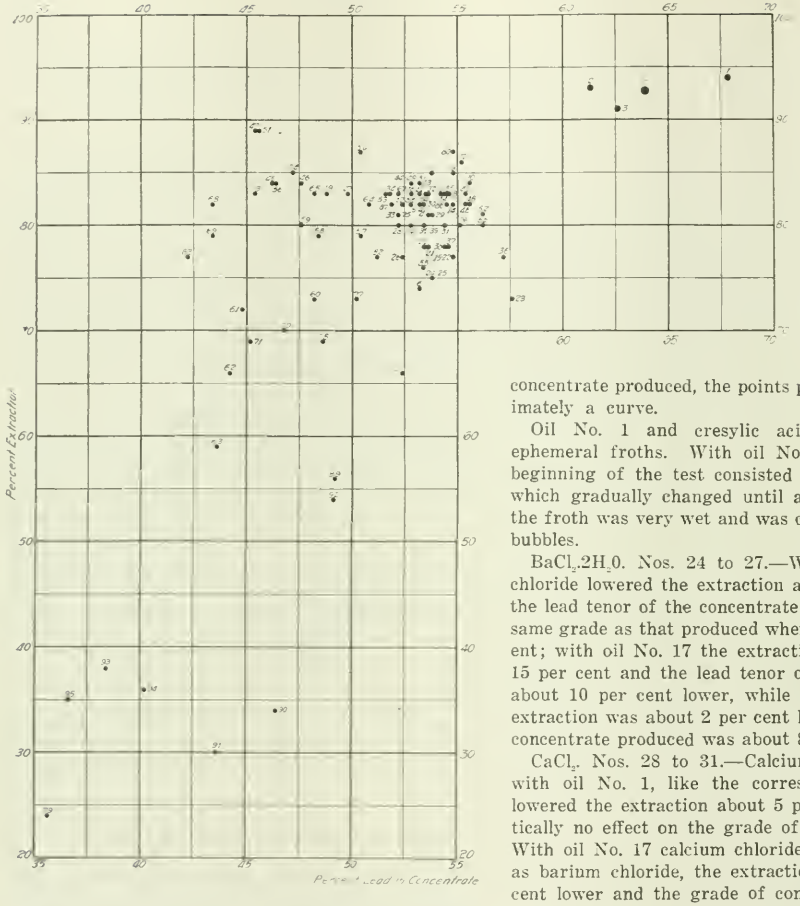

CHART 11. ADDITION AGENTS IN FLOTATION. EFFECT OF CHLORIDES ON THE FLOTATION OF GALENA WITH GENERAL NAVAL STORES FLOTATION OIL NO. 17

of concentrate was about 10 per cent low, while with cresylic acid both the extraction and the grade of concentrate were lowered about 5 per cent. The characteristic froth produced by these chlorides consists of large bubbles which break up quickly.

Alkaline Earth Chlorides

HCl. Nos. 4 to 7.—Hydrochloric acid when used with oil No. 1 lowered the extraction about 5 per cent, while it had practically no effect on the lead tenor of the concentrate. The quantity of hydrochloric acid apparently made little difference, either on the extraction or the grade of concentrate produced. With oil No. 17 the extraction was lowered about 10 per cent when 5 cc. of the reagent was used and 26 per cent when 50 cc. was used, the results falling roughly in a straight line. The grade of concentrate was lowered about 10 per cent in each test regardless of the amount of the reagent present. With cresylic acid and 5 cc. of hydrochloric acid the extraction was practically the same as when no addition agent was present, but when 50 cc. was added the extraction was lowered about 13 per cent. The lead tenor of the concentrate varied from 4 per cent lower with 5 cc. to 7 per cent lower with 50 cc. With this oil, the greater the quantity of hydrochloric acid used the poorer the extraction and the lower the grade of concentrate produced, the points plotted making approximately a curve.

Oil No. 1 and cresylic acid produced ordinary ephemeral froths. With oil No. 17 the froth at the beginning of the test consisted of large, dry bubbles, which gradually changed until at the last of the test the froth was very wet and was composed of very small bubbles.

$BaCl_2.2H_2O$. Nos. 24 to 27.—With oil No. 1 barium chloride lowered the extraction about 5 per cent, while the lead tenor of the concentrate was practically of the same grade as that produced when no reagent was present; with oil No. 17 the extraction was lowered about 15 per cent and the lead tenor of the concentrate was about 10 per cent lower, while with cresylic acid the extraction was about 2 per cent lower and the grade of concentrate produced was about 8 per cent lower.

$CaCl_2$. Nos. 28 to 31.—Calcium chloride when used with oil No. 1, like the corresponding barium salt, lowered the extraction about 5 per cent, but had practically no effect on the grade of concentrate produced. With oil No. 17 calcium chloride is not so detrimental as barium chloride, the extraction being about 12 per cent lower and the grade of concentrate about 10 per cent lower. With cresylic acid the extraction is about 3 per cent higher than the extraction obtained when no reagent was present, while the grade of concentrate is about 6 per cent lower.

$SrCl_2$. Nos. 32 to 35.—Strontium chloride with oil No. 1 has practically no effect. With oil No. 17 the effect was practically the same as that produced by calcium chloride. With cresylic acid the extraction was lowered about 6 per cent and the grade of concentrate was 7 per cent to 8 per cent lower.

$MgCl_2.6H_2O$. Nos. 36 to 39.—Magnesium chloride has practically the same effect as strontium chloride.

The results obtained with the alkaline earth chlorides and hydrochloric acid were very similar in every respect to those obtained with the alkali metal chlorides.

Metallic Chlorides

$MnCl_2$. Nos. 40 to 43.—The quantity of manganese chloride seems to have practically no effect on the results obtained. With oil No. 1 the extraction was lowered about 4 per cent with practically no effect on the grade of concentrate produced; with oil No. 17 the extraction and the grade of concentrate were about 10 per cent lower, while with cresylic acid the extraction

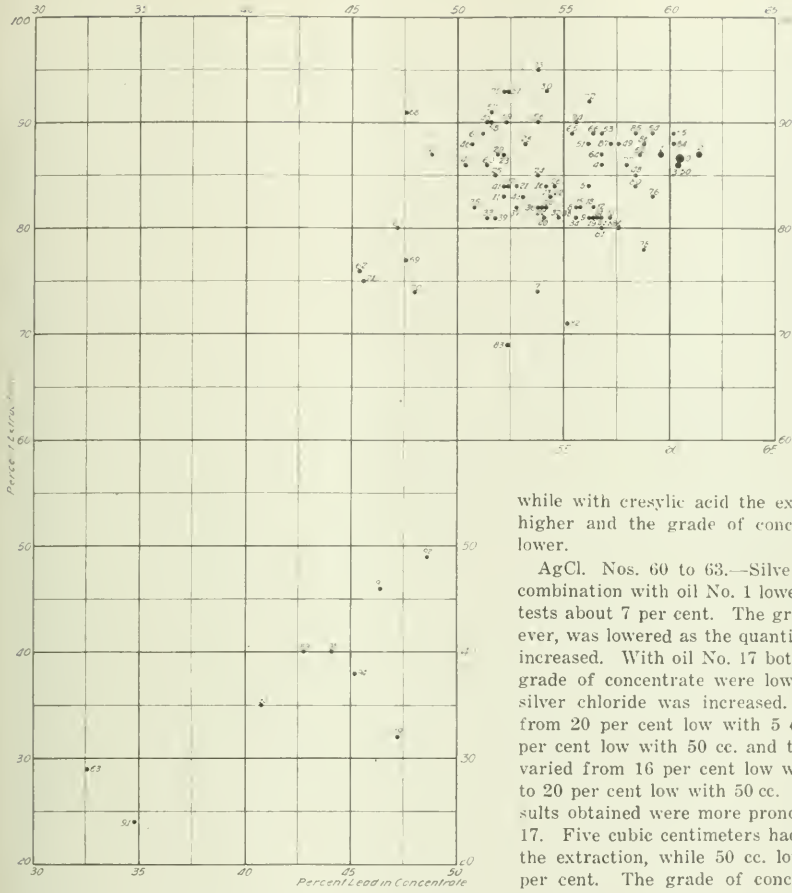

CHART 12. ADDITION AGENTS IN FLOTATION. EFFECT OF CHLORIDES ON THE FLOTATION OF GALENA WITH CRESYLIC ACID

was 5 per cent lower and the grade of concentrate was 6 per cent to 7 per cent lower.

$NiCl_2$. Nos. 44 to 47.—Nickel chloride produced results which were more erratic than any of the previous chlorides. Considering the results as a whole, the extraction is better and the grade of concentrate is lower than with either the alkali metal chloride or the alkaline earth chloride.

$CoCl_2.6H_2O$. Nos. 48 to 51.—The general action of cobaltous chloride is very similar to that of nickel chloride. The results obtained were more erratic with oil No. 1 and cresylic acid than with oil No. 17. With oil No. 17 an increased quantity of cobaltous chloride increased the extraction and lowered the grade of concentrate.

$FeCl_3.6H_2O$. Nos. 52 to 55.—With oil No. 1 ferric chloride lowered the extraction about 4 per cent and slightly raised the grade of concentrate produced; with oil No. 17 both the extraction and the grade of concentrate were lowered 10 per cent, while with cresylic acid the extraction was about 2½ per cent higher and the grade of concentrate produced was about 12 per cent lower.

$CuCl_2.2H_2O$. Nos. 56 to 59.—The effect of cupric chloride, when compared with the effect of previous chlorides, was to produce a low-grade concentrate with little effect on the extraction. With oil No. 1 the extraction was 4 per cent lower and the grade of concentrate was 7 per cent lower; with oil No. 17 the extraction was 12 per cent lower and the grade of concentrate was 16 per cent lower, while with cresylic acid the extraction was 4 per cent higher and the grade of concentrate was 8 per cent lower.

AgCl. Nos. 60 to 63.—Silver chloride when used in combination with oil No. 1 lowered the extraction in all tests about 7 per cent. The grade of concentrate, however, was lowered as the quantity of silver chloride was increased. With oil No. 17 both the extraction and the grade of concentrate were lowered as the quantity of silver chloride was increased. The extraction varied from 20 per cent low with 5 cc. of the reagent to 35 per cent low with 50 cc. and the grade of concentrate varied from 16 per cent low with 5 cc. of the reagent to 20 per cent low with 50 cc. With cresylic acid the results obtained were more pronounced than with oil No. 17. Five cubic centimeters had practically no effect on the extraction, while 50 cc. lowered the extraction 57 per cent. The grade of concentrate produced varied from 9 per cent lower with 5 cc. to 28 per cent lower with 50 cc.

$PbCl_2$. Nos. 64 to 67.—With oils No. 1 and No. 17 lead chloride lowered the extraction 10 per cent and the grade of concentrate 12 per cent. With cresylic acid the extraction was 1 per cent higher, while the grade of concentrate produced was 5 per cent lower.

$HgCl_2$. Nos. 68 to 71.—Mercuric chloride with oil No. 1 lowered the extraction apparently 12 per cent and lowered the grade of concentrate about 18 per cent. With oils No. 17 and cresylic acid the quantity used seemed to have little effect on the grade of concentrate produced, which in the case of oil No. 17 was 19 per cent lower and with cresylic acid 13 per cent lower. The extraction depends on the quantity of the salt used, varying with oil No. 17 between 10 per cent to 23 per cent lower and with cresylic acid between 4 per cent higher and 11 per cent lower.

$AlCl_3.6H_2O$. Nos. 72 to 75.—The quantity of aluminium chloride used seemed to have little effect on either the grade of concentrate produced or on the extraction. With oil No. 1 this reagent lowered the extraction 13 per cent and the grade of concentrate 11 per cent; with oil No. 17 the extraction and grade of concentrate were lowered respectively 10 per cent and 14 per cent, while

with cresylic acid the extraction was raised 6 per cent and the grade of concentrate was lowered 6 per cent.

$SnCl_2.2H_2O$. Nos. 76 to 79.—Stannous chloride had a very detrimental effect on both the extraction and the grade of concentrate produced. Its detrimental action depends on the quantity used, decreasing both the extraction and the grade of concentrate produced, as the quantity of the reagent was increased. With oil No. 1 the extraction varied from 5 per cent lower with 5 cc. of the solution to 46 per cent lower with 50 cc. of the solution, while the grade of concentrate varied respectively from 5 per cent lower to 17 per cent lower. With oil No. 17 the extraction varied from 13 per cent low with 5 cc. of the solution to 69 per cent low with 50 cc. and the grade of concentrate likewise varied from 9 per cent to 28 per cent lower. With cresylic acid small quantities of this reagent had very little effect on either the extraction or the grade of concentrate produced, but when 50 cc. of the solution was added the extraction was lowered 55 per cent and the grade of concentrate was lowered about 10 per cent.

$ZnCl_2$. Nos. 80 to 83.—The results obtained when zinc chloride was used varied greatly with the different oils. With oil No. 1 the extraction and grade of concentrate were lowered 8 per cent and 11 per cent respectively, there being little difference in the results obtained with the various quantities of the reagent. With oil No. 17 the extraction varied between 5 per cent and 15 per cent lower and the grade of concentrate varied between 9 per cent and 22 per cent lower, depending on the quantity of the reagent used. With cresylic acid the extractions varied between 3 per cent and 8 per cent lower and the grade of concentrate between 2 per cent and 8 per cent lower, depending on the quantity of the salt used, the points as plotted making a fairly good curve.

BiOCl. Nos. 84 to 87.—The quantity of bismuth oxychloride used had very little effect on either the extraction or the grade of concentrate produced. With oils No. 1 and No. 17 the extraction and grade of concentrate were respectively 10 per cent and 12 per cent lower. With cresylic acid the extraction was about 2 per cent higher, while the grade of concentrate produced was 2 per cent lower.

UCl_4. Nos. 88 to 91.—Uranium chloride had a very marked effect on the results obtained. With oil No. 1 5 cc. of this salt lowered the extraction and grade of concentrate produced 9 per cent and 6 per cent respectively, while 50 cc. lowered the extraction and grade of concentrate 70 per cent and 29 per cent respectively. With oil No. 17 the extraction varied between 16 per cent low with 5 cc. of the solution to 62 per cent low with 50 cc., and the grade of concentrate likewise varied between 11 per cent and 20 per cent lower. With cresylic acid the extraction varied between 6 per cent low with 5 cc. of the solution to 63 per cent low with 50 cc., and the grade of concentrate likewise varied between 3 per cent and 25 per cent low.

$CdCl_2.2H_2O$. Nos. 92 to 95.—Cadmium chloride as in the case of all previous salts containing cadmium had a very detrimental effect on both the extraction and grade of concentrate produced. With oil No. 1 the extraction varied between 28 per cent and 58 per cent lower and the grade of concentrate betwen 10 per cent and 28 per cent lower. With oil No. 17 the extraction varied between 39 per cent and 58 per cent lower and the grade of concentrate between 15 per cent and 28 per cent lower. With cresylic acid the extraction varied between 36 per cent and 49 per cent lower and the grade of concentrate between 12 per cent and 16 per cent lower. The experimental work with cadmium salts up to the present time indicate that very small quantities of cadmium have a very marked detrimental influence on both the extraction and the grade of concentrate produced by flotation. Results also indicate that additions of larger quantities of the salt have no more effect than the smaller quantities.

There was nothing special in the action of the chlorides other than the general effect on the extraction and grade of concentrate. The froths are very uniform, generally consisting of small or medium sized bubbles, which break up very quickly.

Missouri School of Mines and Metallurgy,
Rolla, Mo.

Increased Output of Crystalline Graphite.—The production of crystalline graphite in the United States was increased last year about 24 per cent, amounting to approximately 6800 tons, against 5466 tons in 1916. About 60 per cent of the output in 1917 was flake graphite suitable for making crucibles; the remainder was dust graphite. These figures are a preliminary estimate of the Geological Survey.

The production from the Alabama field, instead of being more than double that of 1916, as would have been expected from the large number of new companies entering the field, shows only a slight increase, for owing to freight embargoes the Alabama producers have been unable to market their product. The other producing fields have made notable increases in production but not sufficient to increase greatly the total output.

The imports of crystalline graphite in 1917 as shown by the records of the Bureau of Foreign and Domestic Commerce for the first ten months and as estimated for November and December, amounted to more than 32,000 tons, of which 25,000 tons came from Ceylon. If the Alabama producers could have had free access to the markets a much larger proportion of our needs could have been supplied from domestic sources.

The value of the graphite produced in 1917 is considerably greater than that produced in 1916, for No. 1 flake has commanded a higher price and many of the mills marketed a larger proportion of this grade in 1917 than formerly.

Figures showing the production of amorphous graphite are not yet available.

Chimie & Industrie.—The first issue of *Chimie & Industrie*, the official journal of the recently formed Société de Chimie Industrielle of France, has appeared. It contains a statement on the aims of the society, its program and organization and the fields to be covered by the journal, which will appear monthly. The editor-in-chief is Prof. Camille Matignon of the Collège de France. Judging by the appearance of the first number and the advertisements contained therein, the journal should prove successful. It has indeed made a very good start. The best wishes of this journal go to our brothers in France and we look forward to seeing it play an important part in the industrial development of that country. The recently formed New York Section of the Society now has about 165 members.

Ceramics and the War*

By Edward W. Washburn†

At the time this building was dedicated last year one of the professors at a neighboring university happened to see one of the dedication pamphlets bearing a picture of the new Ceramics Building upon it, and he was curious as to why such a large building should be constructed for such a subject as ceramics. It appears that he was under the impression that the term "ceramics" was applied to the art of deciphering the ancient cuneiform inscriptions which the Assyrian and Babylonian peoples made on clay tablets. This incident illustrates in a way the condition which exists in the mind of the average man regarding the subject of ceramics. Either he has never heard the term, and consequently it conveys no meaning whatever to him, or else he perhaps associates it only with the beautiful vases and the ancient pottery which he sees in the museums. Certainly the average man would be astonished if he were told that the science and art of ceramics was of the utmost importance in the prosecution of a war. It is nevertheless a fact that modern warfare could not be conducted without the assistance of the ceramic engineer and artisan, and I wish to point out briefly at this time some of the fields in which ceramics is indispensable to a nation engaged in war.

I will begin my subject by telling you a story of the way in which the importance of one branch of this subject was first brought home to the English people early in the war. Not long after the war started, a committee from the British steel manufacturers waited upon the British government and stated that as far as they could determine their factories would be able to continue operation for only a few weeks longer, after which they would be obliged practically to shut down. Of course, that was a very serious state of affairs for a country just entering upon a big war, and the government and people would naturally be alarmed at such a prospect, and curious as to the causes which produced it. Now, if one were to ask the average citizen to hazard a guess as to a probable cause for the closing down of the steel works of a country he would probably think of labor troubles or transportation difficulties, or perhaps lack of ores or fuel, or other raw material; but I venture to say that the true source of the difficulty which confronted the English manufacturers would never be suspected. As a matter of fact, the crisis in which the British manufacturers found themselves was caused by the fact that the supply of chemical glassware in England was approaching exhaustion, and since all of this glassware had been imported from Germany, there appeared to be no way of renewing the supply. Now, a modern chemical laboratory cannot be operated without a variety of different kinds of vessels and apparatus constructed from a special kind of glass, and when the laboratory of a steel works ceases to function the plant can no longer operate, since it is operated entirely under the control of its laboratory. The chemists of Great Britain were appealed to in the crisis, and they immediately set to work to find out how to make chemical glass, and fortunately they were able to solve the problem before the crisis became acute; but for a while the government was very much alarmed, and at one time an inventory of all the chemical glassware in the kingdom was contemplated so that it could be confiscated, if necessary, for the national needs. Before such a necessity arose the chemists had found out how to make a sufficiently good grade of chemical glassware to meet the immediate needs.

Curiously enough, about the same time the coal miners were confronted with a similar situation, and here again the source of the trouble was glass. The kind of glass used in miner's lamps had been obtained entirely from Germany, and since the safety of hundreds of miners was dependent upon the heat-resisting power of the glass in their lamps, it was evident that this problem also required an immediate solution. Both of these problems are in the realm of ceramic chemistry, and both of them were solved by the British chemists before the situation became a dangerous one.

The immediate appearance of these two, so to speak, ceramic crises in England called attention to a situation which had existed in England for a long period of time. During the decade immediately preceding the outbreak of the war, British chemists and physicists had repeatedly directed the attention of the public to the importance of scientific education and scientific research, and had warned the country of the dangers which threatened both its industrial and its political life because of the failure of the government to appreciate the backwardness of the nation in this respect, and because of the resultant dependance of the country upon Germany for many essential materials. It is well known that the backbone of Germany's war strength has been her chemists, and a large element in the weakness of Great Britain early in the war arose from her state of scientific unpreparedness in many chemical lines and the failuse of the government to make sufficient use—even after the outbreak of the war—of the chemical resources which the nation already possessed, and the utter ignorance on the part of the British officials of some of the simplest chemical facts of first importance in the conduct of the war. One illustration of this ignorance occurred during the early days of the war, when the British government prepared its first list of contraband of war. This was before the days of the food blockade, when foodstuffs were still allowed to be sent into Germany. All manufactured munitions and all materials which were used in the manufacture of munitions were declared contraband of war. Nevertheless, under the guise of food, large quantities of lard and other fats were imported by Germany without any attempt on the part of Great Britain to prevent it. Finally the attention of the government was called to the fact that it was permitting Germany to import all the lard which she wanted, and that the Germans were making munitions of war out of the lard. Now, lard is one of the principal sources of glycerine, and when glycerine is treated with a mixture of sulphuric and nitric acids a rather important article known as nitroglycerine is the result. But apparently no one connected with the British government was aware of this fact, and when attention had been called to it by the chemists of the country one of the public officials of Great Britain is said to have stated in defense of the government that the manufacture of nitroglycerine from lard was *a recent German discovery*, and that consequently the British government could not be expected to know of it.

*A talk before the students of the Short Course in Ceramic Engineering at the University of Illinois, Jan. 11, 1918.

†Professor of Ceramic Chemistry, University of Illinois.

This example illustrates fairly well the condition of affairs in Great Britain in the early days of the war. These conditions have, of course, been remedied to a large extent since the war started, because English scientific unpreparedness, as contrasted with Germany's high state of scientific preparedness, was not in any way due to the fact that Germany had better chemists than England, for such was not the case; the difference was due to the fact that the German government and people appreciated the importance of scientific education, scientific research, and the application of science to industry, while the British government and her people did not.

But to return to the subject of ceramics and the war. In addition to the problems of chemical glassware and of heat-resisting glass already mentioned, one other glass problem of still greater importance had to be solved. I refer to the matter of optical glass, about which we have heard a great deal since our own country entered the war. Optical glass, as you know, is needed for the manufacture of telescopes, binoculars, officers' field glasses, range finders, and telescopic sights for the artillery, submarine and trench periscopes, photographic lenses and photographic plates for army and navy observation purposes, and X-ray bulbs and microscopic lenses for the medical and sanitary corps. Previous to the war, Germany manufactured about 100 different kinds of optical glass, which she shipped to all parts of the world. England manufactured about 20 different kinds, and the United States manufactured none whatever. The twenty kinds manufactured by England were not sufficient in number, nor was the output anywhere near sufficient to supply the British army and navy. In fact, in addition to stimulating the manufacture of optical glass the British government was obliged to collect from private individuals large numbers of field glasses and small telescopes, and even as recently as six months ago the output of optical glass, although many times greater than it was before the war, was still apparently insufficient to provide for all of the glasses needed by the army and navy.

When America entered the war she was, as you know, also brought face to face with this same problem in ceramic chemistry, and the country was obliged to turn to its chemists for assistance. Under the able direction of a special committee on optical glass, composed of Major H. A. Millikan, professor of physics at the University of Chicago; Dr. Arthur L. Day, director of the Geophysical Laboratory of the Carnegie Institution; and Dr. S. W. Stratton, director of the U. S. Bureau of Standards, research in the manufacture of optical glass has been vigorously prosecuted both in the Geophysical Laboratory, under Dr. Day's direction, and in the Bureau of Standards' Laboratories at Pittsburgh, under the direction of Mr. A. V. Bleininger. As a result of these investigations, and with the co-operation of some of the largest glass manufacturers of the country, there is now being manufactured in America all of the different kinds of optical glass which are most urgently needed by the army and navy; and although the output is, as yet, not quite as large as we would like to have it, the situation is improving every day, and the crisis with which the country was threatened may be considered as safely past. In fact, there seems to be no likelihood that the glass situation, as a whole, will ever become as acute in this country as it did in England, where a special officer having the title of Director of Optical and Glassware Munitions was appointed and placed in charge of all glass production, purchase and sale in the United Kingdom. No kind of glass or glassware can be manufactured, bought or sold in England without a license from this officer.

The second big field of ceramics which is of fundamental importance to the industrial life of a nation, both in time of war and in time of peace, is the field of refractory materials. Every industry which uses high temperatures in any part of its process has a more or less acute problem of refractory materials. Even where the only high temperature employed is in the power house of the plant there still exists a rather important ceramic problem, for the life of a boiler setting depends upon the proper adaptation of the refractory material employed to the chemical action of the fuel gases and to the abrading action of ashes and cinders, as well as to the direct action of the high temperature itself. In industries such as the metallurgical industries, which employ very high temperatures, the problem of refractory materials is, of course, of still greater importance. In fact, it is not too much to say, that, other things being equal, the rate at which a country can produce munitions of war is very closely connected with its supply of suitable refractory materials because the character of such materials determines the frequency with which furnaces have to be closed down for relining. A great many refractory materials, such as fire brick and other fire-clay articles, silica brick, chrome brick, magnesite brick, dolomite, bauxite, graphite, porcelain, alundum, zirconia, etc., are manufactured and employed in the different industries, each industry having its own special refractory problems, since the conditions of temperature, chemical action, abrasion, etc., are different in the different industries, and the refractory has to be adapted to withstand the special conditions of each industry.

Among the porcelain refractories may be mentioned the special electrical insulators for high-tension transmission lines, as well as the insulators for ordinary voltages in buildings, cars, and on ships; sanitary porcelain; the porcelain employed by the chemist in the form of crucibles, casseroles, etc.; the particular variety of porcelain used in protecting pyrometer tubes; and the porcelain spark plugs which are so important in the aeroplane. Indeed, the length of time which an aeroplane can remain in the air is not infrequently determined by the character of its spark plug, since an improperly constructed spark plug deteriorates rapidly under the influence of the high temperatures to which it is subjected during the operation of the engine. We thus see that ceramics has an important and close connection even with the subject of aviation. In the case of chemical porcelain and the special porcelain for manufacturing pyrometer tubes, the ceramic chemists of this country have had to discover the methods of manufacturing these materials, since they were purchased from Germany previous to the war. Fortunately, the investigations of our ceramic chemists on these two subjects have been entirely successful, and we can manufacture, and are manufacturing, porcelain of this character which is just as good, if not better, than that which was previously imported from Germany. Among other ceramic products which are more or less important in time of war the following may be mentioned:

1. Enameled iron products, such as autoclaves, kettles, and evaporators, which are used in ammunition manufacture. The manufacture of an enameled lining which will stand up under the pressures, temperatures and chemical action to which it is subjected in these processes is quite a problem. The less important application of enameled ware, in the form of cooking vessels in the army canteens and kitchens, may also be mentioned.

2. The manufacture of abrasive wheels, of which large numbers are used in the manufacture of artillery, is an important ceramic industry, and the proper bonding material for use in the manufacture of such wheels is a ceramic problem which still requires considerable investigation.

3. The purification and treatment of ceramic raw materials, such as clays, sand, bauxite, etc., in order to adapt them for the needs of the manufacturer, is also one of the most important ceramic subjects at the present time.

The foregoing outline of ceramics and its relation to warfare will serve, I hope, to convey a general idea of the many and varied ways in which the ceramic industries of the country are of fundamental importance to the nation's welfare and to its ability to properly prepare itself for war. The need for scientifically trained ceramic chemists and ceramic engineers has never been so great as it is at the present time. The country could easily absorb ten times as many technically trained men of this character as it is now producing, and it ought to be the duty of every man who appreciates the situation to do everything he can to stimulate the production of such men. I think one of the reasons why so few college men take up ceramics as a life work is because of the ignorance on the part of the general public as to the significance and importance of this subject, and I hope that each one of you will make it a point to call the attention of the young men in your own community to the importance of this field and to the excellent prospects which it holds out to a young man who will properly train himself in this subject. There ought to be a very rapid growth in all of the ceramic schools of the country during the next ten years, but I am certain that even the most rapid growth which we are likely to have will still fall far behind the still greater growth in the demand for such men, because of the fact that the great ceramic industries of the country, employing thousands of men, and representing an investment of many millions of dollars, are just beginning to wake up to the importance of applied science and to the necessity of employing technically trained men for directing their operations and solving their difficulties.

Great as is the present demand for such men, I am sure that in the next decade we are going to see this demand multiplied manyfold, and I hope that every one of you will on every possible occasion make known to the young men of your acquaintance the excellent prospects which the career of ceramic chemist and ceramic engineer holds out to them.

Nichols Medal Award—The jury of the Wm. H. Nichols Medal of the New York Section of the American Chemical Society awarded the medal for the calendar year 1917 to Treat B. Johnson of the Sheffield Scientific School of Yale University, for his work on pyrimidines.

Sulphuric Acid Production in 1917

More sulphuric acid was produced in the United States in 1917 than in any previous year, according to the Geological Survey. A moderate estimate shows that the increase in the production of acid of all strengths in 1917 over that in 1916, stated in terms of 60-deg. B. acid, amounted to at least 600,000 tons.

It is not yet possible to state accurately the production of sulphuric acid in 1917 according to strengths, for some of the companies that produce 50-deg, 60-deg. and 66-deg. acid have reported their entire production together and so stated it as if they had made only 100 per cent acid. Now, 100 per cent sulphuric acid is above 66 deg. B. and is here reported as "stronger acid," but, in view of the fact stated, a certain quantity of the stronger acid reported should really be carried as acid having a strength of 66 deg. B. or less. However, as no data are available to show the proper distribution of all the acid made in 1917, the following table has been prepared as if the reported production were the actual production:

Strength of Acid	1917 Short Tons	1916 Short Tons
50 deg.	2,306,372	1,829,471
60 deg.	1,187,704	1,119,753
66 deg.	850,006	1,580,100
Stronger acid	1,190,019	443,332

In comparing the production reported for 1917 with that for 1916, only acids of similar strength should be compared. For instance, the amount of acid of 66 deg. B. reported for 1917, namely, 850,000 tons, is equivalent to 1,290,000 tons of 50-deg. acid. In other words, the sum of the amounts of the different acids as given above for 1916 and 1917 should not be compared to show the output in the two years, for the great increase in the output of the stronger acids would represent a much larger increase in that of the weaker acids.

The condition of the market for sulphuric acid in 1917 is reported to have been on the whole even better than in 1916, and the value of the product was considerably higher than it was during that year of high prices. Some companies have had difficulty in obtaining sufficient sulphur ore and many of them have been compelled to change from pyrite to sulphur burners. Experiments in the greater utilization of pyrrhotite have been carried on and attempts have been made to find domestic deposits of pyrite that can be used if the supplies of foreign ore are curtailed under the conditions imposed by the war.

Nearly 98 per cent of the manufacturers reported their production, and that of the others was estimated from previous records. It is believed that the totals of these preliminary figures will approximate very closely the final figures, which will be made up when the complete returns are received, although the quantity of acids of different strengths as stated may require considerable readjustment.

Red Cross Wants Used Tracing Cloth.—The American Red Cross is desirous of having manufacturers, draftsmen and all those having old tracing cloth which is of no value to them send it to a local laundry or Laundry Owners' Association, where it will be washed and delivered to the Red Cross. An appeal has been made to laundries to undertake the work and it is felt that considerable linen, of which there is a shortage, can be furnished in this way.

The Trumble Oil-Refining Process

AT the annual meeting of the American Institute of Mechanical Engineers, in December, N. W. THOMPSON of the Simplex Refining Co. of San Francisco presented a description of a new oil-refining process known as the Trumble process. The chief advantage claimed for the process is the conservation of heat. It was stated that a plant operating under this system was doing—on 1.1 per cent of the crude oil run through as fuel—more work than large oil refineries using as fuel 4 per cent of the crude oil.

In Fig. 1 is shown a Trumble evaporator, to which in this case is connected an evaporator column. The evaporator consists of a closed cylindrical metal shell, vertically disposed, to which heat is applied from the outside in any convenient manner, as, for example, by flue gases or by vapors from another evaporator.

Inside the evaporating chamber is arranged a central vertical pipe having umbrella-shaped devices attached

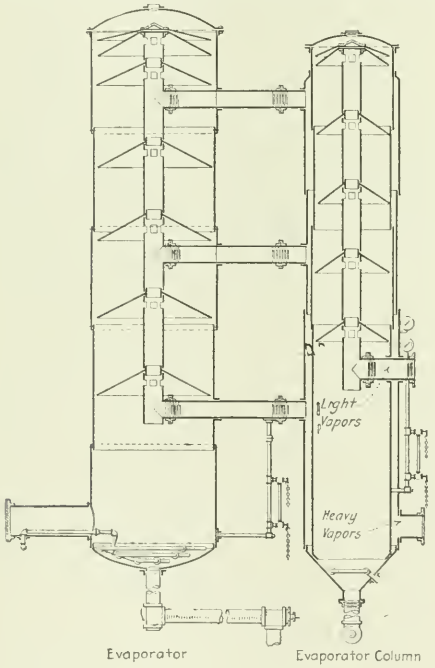

FIG. 1. EVAPORATOR AND EVAPORATOR COLUMN

thereto at intervals, which are called "spreader hoods," so that oil fed to the apex of these hoods will flow down over their sides in a thin film after the analogy of rain flowing down the outside of an umbrella. The lower edges of these hoods are at a little distance from the sides of the wall of the evaporating chamber, and in operation the oil flows down and over the hood and strikes against the interior wall of the evaporating chamber and flows down the wall in a thin continuous film.

In case any of the oil should not strike against the wall in the evaporating chamber, but should drop off the edge of the hood and fall vertically; or in case there should be a tendency to bubbling or foaming on the wall of the evaporating chamber whereby a portion of the oil may be thrown back toward the center of the evaporating chamber, such oil will be caught by the next spreader hood and will flow down the surface thereof, thereby insuring an ultimate spreading of the oil on the wall of the evaporating chamber.

The oil to be operated on is fed through a supply pipe to the top of the evaporating chamber, and discharges downward on the apex of the uppermost hood. The oil then flows down this hood in a thin stream, and is delivered against the interior wall of the evaporating chamber as herein above described.

The centrally arranged vapor take-off pipe in the evaporating chamber, to which the spreader hoods are attached, is provided with perforations underneath each of the hoods, and through these perforations the vapors pass from the evaporating chamber into the vapor take-off pipe. Located in this vapor take-off pipe are lateral branch pipes, and these branches extend through the wall of the evaporating chamber to the outside of the apparatus.

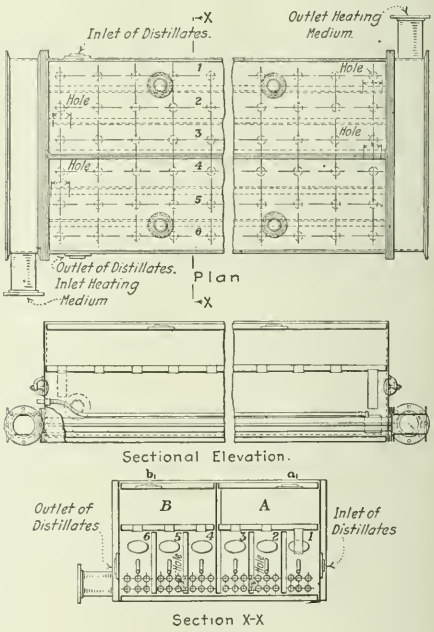

FIG. 2. SEPARATOR

Fig. 2 shows the construction of the separator. This is a re-run still for distillates from bottoms of dephlegmators, or from any other source, if these need fractionating. The distillate flows into compartment (1) over a number of pipes through which a heating medium is passed, either residuum or vapors, as the case may be, and then passes through an opening at end of compartment (1) into compartment (2) and back through compartment (3) and so on, leaving at the end of compartment (6). The vapors evolved in compartments (1), (2) and (3) pass through openings into vapor compartment *B* and out through opening b_1 to condenser, etc.

The manifolds on the ends of the separators are pro-

vided with covers having stuffing boxes through which valves are operated to regulate the flow through tubes in each compartment, thereby controlling the heat in these compartments.

The flow of the crude oil through the plant is indicated by the flow sheet in Fig. 3. The oil enters through a 6-in. line and is used as a cooling medium in the six coolers shown. These coolers are of the horizontal tubular type, 30 in. in diameter, with sixty-two 2-in. by 18-ft. tubes. The oil enters at the bottom and passes through the tubes, making four passes, and comes out at the top and goes into a header, through which it passes into the four heat exchangers or coolers for the residuum.

These heat exchangers are 48 in. in diameter, and have 178 2-in. by 18-ft. tubes. The crude oil enters the first heat exchanger at the bottom and passes through the tubes, making six passes, and out at the top into the bottom of the next exchanger, and so on, to the heater pipes, where it is split in two, each half passing in series through seventy-two $18\frac{3}{4}$-ft. lengths of 4-in. pipe, flowing back and forth and upward at all times, and then into the top of the evaporator, where it flows down the sides in a thin film.

The oil, in passing through the heater pipes and evaporator, is heated by the flue gases. The vapors evolved are separated in the evaporator and taken care of later. The oil is maintained at a constant level in the bottom of the evaporator and runs out of the bottom of it as residuum. A perforated steam coil is placed in the bottom of the evaporator under the liquid and superheated steam is passed through it in order to drive off any of the lighter distillates which may drop back from the vapors. However, very little steam is necessary in this case, as the heat losses are supplied by the flue gases.

After leaving the evaporator the residuum is used as a heating medium for redistilling the distillates passing through separators, and then flows through the heat exchangers counter-current to the crude oil. The residuum enters the first heat exchanger at the top and makes two passes around the tubes and out at the bottom, then into top of the second exchanger, and so on through the five heat exchangers and through a standpipe, which is vented, and which controls the head of residuum in the bottom of the evaporator, and then to the storage tanks.

The vapors from the central vapor column of the evaporator are taken out through a shell and connected into a header. The vapors pass from this header through an oil catcher similar to a steam separator, the condensate passing out of the bottom of it into the bottom of the evaporator. They then pass through six large dephlegmators in series, flowing into the bottom of each and out at the top. In each dephlegmator a partial condensing of the vapor takes place, thus forming a liquid in the bottom of that particular dephlegmator. From some of the dephlegmators this condensed liquid is a ready product—from others it is just between two different products.

A system of water circulation is used as a cooling medium for the vapors from the dephlegmators and separators. The vapors are cooled in vertical tubular condensers, and about twenty barrels of water are required per barrel of distillate cooled. Superheated steam is used in the bottom of the evaporators, separators and dephlegmators as an agitator to relieve the lower boiling point fractions from the bottom. About 30 lb. of steam are used to each barrel of distillate produced.

Mr. Thompson said it is possible to save by proper distribution of the heat available around the oil refineries in the United States at least 2 per cent of the total crude oil put through these refineries. He said there are large oil refineries operating to-day that are using as fuel 4 per cent of the crude oil run through them to do less work than the plant described is doing on 1.1 per cent of the crude oil run through as fuel, and the losses due to non-condensable gases, etc., are 2 per cent against 0.75 per cent.

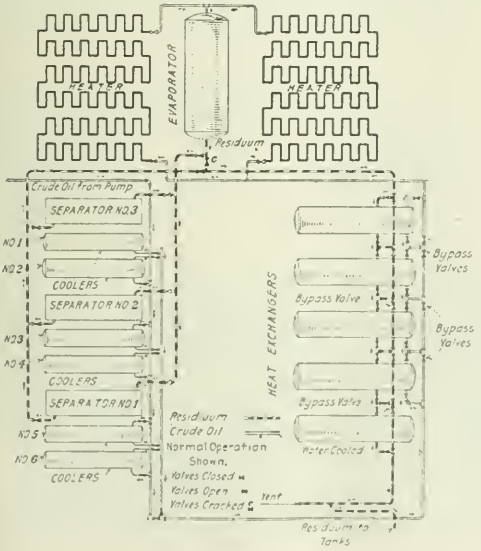

FIG. 3. CRUDE OIL AND RESIDUUM SYSTEM

Cost of Refining Gasoline.—The Federal Trade Commission has obtained data on the cost of producing gasoline in August, 1917. The figures are the result of distributing the actual total refinery costs to the various refined products on the basis of the values of the various products. The costs are based on 55 refineries in all parts of the United States. They are given in the following table:

REFINING COST PER GALLON OF GASOLINE

	Low Cents	High Cents	Representative Cents
1—NEW JERSEY AND EASTERN TERRITORY			
Cost of crude oil	12.0784	13.9575	12.7348
Cost of refining	2.0271	3.9570	4.8836
Total	14.1055	17.9145	17.6420
2—INDIANA AND NORTH MISSISSIPPI VALLEY			
Cost of Crude oil	9.8212	12.8827	11.5120
Cost of refining	1.3620	3.8621	2.1630
Total	11.1840	16.7448	13.6750
3—OKLAHOMA			
Cost of crude oil	9.8801	15.2620	11.1860
Cost of refining	1.5196	2.3740	3.4856
Total	11.4000	17.6360	14.6706
4—GULF COAST			
Cost of crude oil	11.5670	14.5774	13.6608
Cost of refining	.8520	1.7579	1.8074
Total	12.4190	16.3353	15.4682
5—CALIFORNIA			
Cost of crude oil	9.8683	12.2033	11.7160
Cost of refining	1.8743	4.3112	1.7800
Total	11.7426	16.5145	13.5200

Plate-and-Frame Filtration

By D. R. Sperry

FILTRATION within a filter-press may be carried on by means of plates and frames.

Flush Plates

In Fig. 1 is shown a filter plate which can be used only with frames. It will be noted that this kind of plate appears somewhat like the recessed type. The feed-channel is formed by an eye in the upper corner, but is plainly not to be used with grommets. Fig. 2 shows this plate in cross section. Here it can be observed that there is practically no recess in the surfaces whatever and that the hole in the upper corner, called an eye, is much smaller in diameter than that found in the recessed type of plate. The surface surrounding the hole is also flush with the packing surfaces of the plate and has no connections with the filter surfaces or interior of the plate. The grooves on the filtering surfaces lead directly to the outlet, precisely as is the case in the recessed plate. This plate is distinguished from the recessed type of plate by the name of "flush plate."

Frames

In Fig. 3 is shown a frame used in conjunction with the flush type of plate. In general this consists of a flush plate without a center panel. In other words, if the center of a flush plate be cut away up to the packing surfaces, it would have the same general appearance as a frame. In Fig. 4 a frame in cross-section is shown Especial attention is called to the fact that the corner eye has a connection to the interior of the frame and does not go merely straight through from packing surface to packing surface as is the case in a flush plate.

Clothing

In order to use a flush plate-and-frame filter-press, the plates and heads are first clothed. To do this cloths are cut for each plate which are long enough to lay over the top of the plate and extend over each filter surface and beyond the packing surfaces. A hole is cut in the cloth where it covers the eye in the plate. A cloth cut and ready to be applied to a flush plate is shown in Fig. 5.

FIG. 1 FIG. 3 FIG. 5

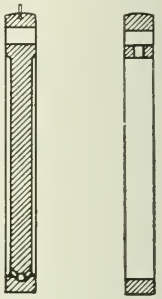

FIG. 2 FIG. 4

A photograph of a cloth in position over a flush plate, but partly lifted to show plate surface, is given in Fig. 6. Two locating pins are placed on the top edge of each plate by means of which the filter cloth is held in position and kept from falling. These are called dowel pins.

Clothing the Heads

When the plates are thus clothed it is necessary to cut smaller cloths to place over the filter and packing surfaces of the heads. The cloth on the slide head has no hole cut in it, as none is required. The one on the fixed head, however, has a hole cut in it where the cloth covers the inlet eye. Photographs of slide and fixed heads showing how the cloths are applied are shown in Fig. 7 and 8. It should be understood

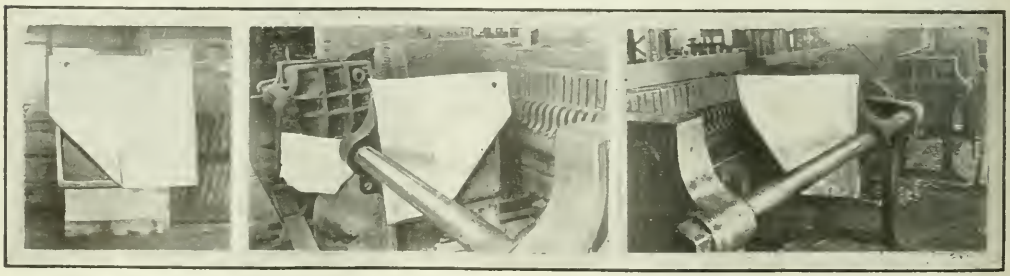

FIG. 6 FIG. 7 FIG. 8

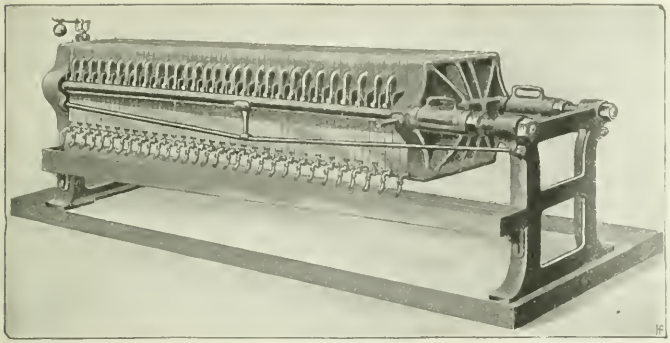

FIG. 9

that dowel pins are supplied on the upper edge of the heads to hold the cloths in position.

Principle of Operation

When all of the plates and both heads are clothed, the plates and frames are placed within the filter-press alternately, that is, a frame is placed between each

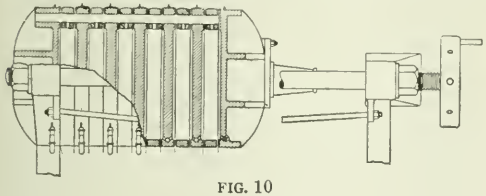

FIG. 10

pair of plates and betwen plates and heads. Thus there is always one more frame than there are plates. A filter-press of the flush plate-and-frame type with all the plates and frames in position is shown in Fig. 9. The plates can be easily distinguished from the frames by the cocks which are on the plates only.

The eyes in the plates and frames are so located that

FIG. 11

when they are in the filter-press they register with each other, beginning with the eye in the fixed head. In other words, if one were to look in the feed inlet on the fixed head, it would be found that a continuous channel is formed by the eyes, running the whole length of the filter-press. Tapping into this channel would be, of course, the connections leading to the interior of the frame.

A cross-section of a flush plate-and-frame filter-press when fully clothed is shown in Fig. 10. Here the channel formed by the eyes in the plates and frames is clearly discernible. The connections or ports to the interior of the frames are plainly evident and their purpose can be soon understood. When the filter-press is closed the material to be filtered is introduced into the feed inlet. The substance runs the entire length of the filter-press, stopping at the slide head, where the absence of an eye therein prevents further progress. As the material flows along the channel it drops into the interior of each frame, eventually completely filling the same. When this happens there is no way for anything to escape except through the cloth. The liquid does the latter and upon emerging on the opposite side of the cloth is conducted along the grooves of the plate surface directly to the outlet corner and out via the cocks. The solids, unable to pass through the cloth and the accumulated

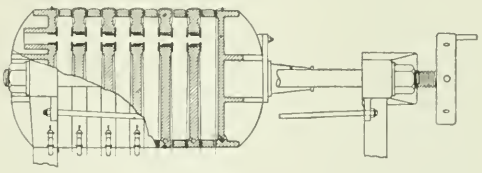

FIG. 12

solids, are retained within the frame. Eventually the frame becomes completely filled with solids and the filter-press is said to be filled. When this has occurred, the material to be filtered is no longer fed into the filter-press and the screw of the filter-press is loosened. The slide head is then pulled back as far as it can go and the adjacent frame slid up and cleaned of its contents of cake. The first plate is then drawn up and the next frame cleaned, and so on, until all of the frames are relieved of their contents. When this is completed, the empty frames and plates are slid back into their proper positions for the next fill.

Frames With Grommet Feed Plates

Frames having no eyes whatever can be used in conjunction with plates having the grommet type of feed. Such a frame is shown in Fig. 11. It can be readily understood how a frame of this type could be inserted between plates of the recessed type and have the effect merely of increasing the cake thickness or chamber capacity. In case the plate were not made recessed but flush, still retaining the grommet feed, the eyeless frame could still be placed between adjacent plates and form a chamber in a somewhat similar manner to that done in the flush plate-and-frame type. A cross-section of a grommet flush plate-and-frame filter-press is shown in Fig. 12. The plates, frames and heads are clothed in a manner similar to that described for the recessed type of plate. A study of Fig. 12 shows that a channel from end to end of the filter-press is formed

by the grommets and the interior of the frames. The end of the channel is formed by the slide head, which has no grommet hole. When the material to be filtered is fed into the inlet, it runs the full length of the filter-press through the grommets and frames. In so doing it fills the interior of each frame. The pressure exerted upon the material by the pump or whatever feeding device is employed, causes the liquid to flow through the cloth which bounds each frame, onto the plate surface back of the cloth and thence via the grooves to the cock placed on the lower corner. The manner of opening and cleaning the filter-press is similar to that described for the flush plate-and-frame type.

Batavia, Ill.

Synopsis of Recent Metallurgical and Chemical Literature

Absorption of Gold in Bone-Ash Cupels.—F. P. DEWEY presents the results of four years' observations at the mint, in a paper entitled "Bone-Ash Cupels," to be presented at the February, 1918, meeting of the American Institute of Civil Engineers. In all, about 100 varieties of bone ash have been tested, and probably 10,000 or more used cupels have been assayed. The result of this investigation is a most emphatic warning against drawing conclusions regarding cupels and cupellation from insufficient data. From the vast accumulation of data now on hand, I can pick out isolated illustrations here and there to support any reasonable supposition and also a great many unreasonable and contradictory ones regarding the subject. Again I can pick out many apparent exceptions to every general rule.

The second result is to emphasize the difficulty of carrying on several sets of cupellations under even approximately the same conditions.

The third result is that rigid conclusions regarding bone ash, cupels and cupellation call for such a vast amount of painstaking detailed work under such onerous conditions that the game is scarcely worth the candle, especially as the customary variations occurring in practical work will nullify many such conclusions.

Finally, then, the results of this work cannot be dealt with in any dogmatic way, but they must be applied in a general and practical way with reasonable consideration and caution.

There have been many investigations of cupels and the most diverse views have been expressed, the extremes being the statements of Lodge[1] that every cupel has some effect upon the loss in assaying telluride ores and of the Campredons[2] that coarse and fine and hard and soft cupels all give the same loss of silver when cupelling the same weights. The truth lies between these statements and much nearer the latter. In a vast majority of cases the influence of the cupel is not dominant and is outweighed by other conditions, particularly the temperature of the cupelling bead.

[1]R. W. Lodge: Assaying Telluride Ores for Gold. *Technology Quarterly* (1899), 12, 171.

[2]G. Campredon: Importance des différentes causes de pertes d'argent à la coupellation. *Revue Universelle des Mines*, Ser. 8 (1904), 8, 210.

In following this matter up, for the purpose of increasing the accuracy of our commercial methods of bullion assays, the question of the absorption of gold by the cupel was found to be a most important one and was taken up for investigation. In a lesser degree, the silver absorption is important and interesting, but at present it appears to be far more complicated and much further investigation is required to put the subject upon a satisfactory basis.

In assaying high-grade products giving large assay buttons, the following general conclusions may be drawn: Within wide limits the screen composition of the bone ash is not the dominant factor in cupellation, but the assayer should inform himself as to the grades of ash available and adopt some plan in selecting or mixing his ash. In the same way the pressure used in making cupels is not highly important, although it is well to keep it fairly uniform. There is no necessity to season cupels. In making comparative tests the closest attention must be given to the temperature question, but the temperature of the cupelling bead is for the present beyond either measurement or control, and high general temperature in the muffle may produce wide variations in the absorption of gold in adjoining cupels. The pyrometer is a good guide to the general temperature conditions, but uniformity of pyrometer reading does not mean uniform bead temperature.

In assaying ductile fine gold, for instance, it is evident that the gold absorption by a cupel may be kept down to 0.1 mg. and need not exceed 0.2 mg. Certainly an absorption of over 0.25 mg. should not be countenanced in fine-gold assaying. In the case of coin gold the figures might be increased by 0.05 mg.

The careful assayer should establish standards of cupellation suitable for his particular lines of work and should assay his used cupels from time to time to see that the standards are being maintained. The conditions of the cupellation are far more important in influencing the cupel absorption than the structure of the cupel. When high or erratic losses are shown the used cupel should first be examined for beads. In the absence of beads the other conditions, especially the temperature, should be carefully considered before blaming the cupel.

Iron and Steel

Copper in Medium Steel.—C. R. HAYWARD and A. B. JOHNSTON have presented a paper before the New York meeting (1918) of the American Institute of Mining Engineers on "The Effect of the Presence of a Small Amount of Copper in Medium-Carbon Steel." Two analyses were investigated, as follows:

	High Copper	Low Copper
C	0.380	0.365
P	0.012	0.053
Mn	0.570	0.590
S	0.030	0.048
Cu	0.860	0.030

The bars, turned to ¾ in., were heated to 845-865 deg. C., quenched and drawn in various ways. The unannealed bars were too hard to turn on a lathe. A 7-in. length was therefore used and the ends annealed in a blacksmith's forge to allow the cutting of the threads. During the heating, the center was kept cool

with water. A 2-in. gage length was then ground at the center of the bar.

The results as shown in Fig. 1 and the accompanying table needs little interpretation. The table of tensile strengths shows a striking superiority of the high-copper steel. The yield point and ultimate strength are in every case higher while the ductility is practically the same, although here too the average figures for reduction of area are with one exception slightly higher for the high-copper than for the low. This, however, is offset by slightly higher values for elongation in a majority of the tests in favor of the low-copper.

The hardness tests by both methods show the high-copper steel in all tests to be harder than the low-copper.

The Charpy shock tests show the high-copper steel in all cases to be superior to the low-copper.

In general, the results confirm the work of Ball,[1] Stead,[2] Breuil[3] and Campbell[4] as regards the effect of copper on hardness and tensile strength. They confirm the work of Breuil[3] as regards brittleness and the work of Campbell[4] as regards reduction of area. It is also true, that as Stead has stated, the behavior of the copper steel resembled that of nickel steel.

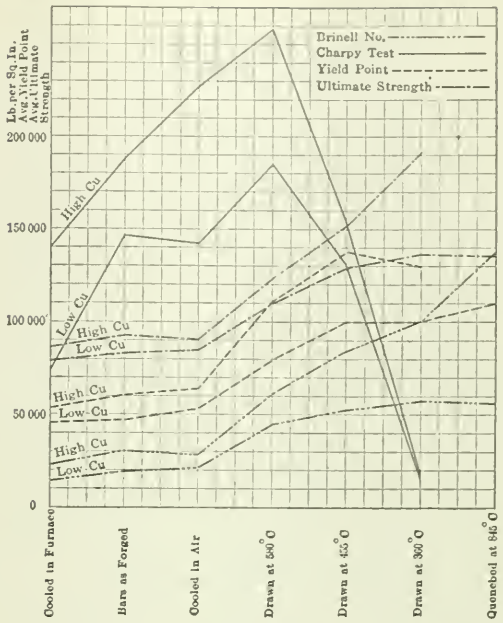

FIG. 1. RESULTS OF TESTS OF STEEL WITH DIFFERENT COPPER CONTENTS

	Per Cent. Reduction		Per Cent. Elongation

Acid-Proof Alloys.—An interesting investigation was recently recorded in *Metall und Erz* by ROLAND IRMANN, according to the *Chemical Trade Journal and Chemical Engineer.*

It is often asserted that electrolytic corrosion tests of voltaic couples of two metals should be a guide as to the corrosion of the alloys of those metals. The investigation by Dr. Roland Irmann of alloys of copper and nickel, to which tungsten and iron were further added, once more disproves this assumption. Much depends upon the proportions and the formation of compounds. Irmann (*Metall und Erz*) was in search of an alloy not to be attacked by strong hot sulphuric acid. He found that an alloy of nickel with 20 per cent of tungsten was much more resistant in this respect than nickel alone; but that the alloy was very difficult to machine and expensive. To introduce tungsten into the nickel, he started from copper-nickel. A voltaic couple of nickel and copper gave an electromotive force of 0.55 volt, which soon went down to 0.25 volt; nickel was dissolved, the copper becoming polarized with hydrogen. Failing to find a more satisfactory binary nickel-couple, he introduced other elements, especially tungsten, into the nickel-copper alloys, studying also the alloys of copper and tungsten. He fused an alloy of nickel-tungsten in an arc furnace and added electrolytic copper; later he used a Helberger furnace, afterward adding more nickel as required. The alloy, consisting of 47 per cent of copper and 4.98 per cent of tungsten, proved highly resistant, and, at the same time, mechanically very strong, giving also the greatest elongation of these copper-tungsten alloys. The electric resistance was greater than that of constantan. Very good results were also obtained with ternary nickel-tungsten-copper alloys. The interesting point is, however, that quarternary alloys, further containing iron, proved far superior to the ternary alloys. This is important in so far, of course, as one may, in preparing the alloys, start from ferro-tungsten instead of having to isolate the tungsten first. By varying the percentage of iron—always low—the qualities of the alloys were suitably modified. When the sulphuric acid is to be used in the cold only, one should take alloys relatively rich in copper and also, to a minor degree, in tungsten and iron. For hot concentrated sulphuric acid Irmann recommends a nickel alloy with 43.65 per cent of Cu, 3.9 per cent W, 1.87 per cent Fe. This alloy also has a very high electric resistance and strength, and can easily be machined; the tensile strength was 28 tons per square inch, and rose to 35.05 tons per square inch in an alloy containing 3.9 per cent of iron. Some of the alloys, however, rather tended to separate in layers during fusion. Irmann also tried to improve German silver (60 per cent Cu, 20 per cent Ni, 20 per cent Zn) by the introduction of tungsten. But the tungsten would not alloy with the zinc, and he could not get more than 0.4 per cent of tungsten into this ternary alloy; the quaternary alloy was, moreover, badly attacked by sulphuric acid.

Recent Metallurgical and Chemical Patents

Roasting and Sintering Apparatus

Combined Sintering and Smelting.—ARTHUR S. DWIGHT of New York City patents a process of sintering and smelting ore which consists of the formation of a continuous sinter cake on the well-known Dwight-Lloyd machine, and continually moving the cake through a slot into a furnace set immediately alongside. By submerging the inner end of the sinter cake into the contained bath its tendency to break by its own weight is counteracted. As the cake enters the furnace it slides between suitable electrical contacts. A sufficient voltage is impressed on the system so that electric current passes through the sinter cake, slag, metal, and furnace bottom to the opposite terminal. The cake is thus heated in four ways: By the heat of sintering, by the current passing through the cake, by conduction and radiation from furnace and contents, and by the arc at the end of the cake. The end of the advancing cake is thus continually melted off, metal, matte and slag separated, and withdrawn. (1,215,635, Feb. 13, 1917.)

Chloridizing Roast for Spent Pyrite.—EDGAR R. SUTCLIFFE of Leigh, England, patents a method for treating ores or residues of especial application to the process of converting copper contained in spent pyrite into cupric chloride for subsequent extraction by wet methods. The ore, together with sufficient common salt, is introduced into a cylindrical kiln *a* through a hopper *f*, and heated to a temperature of 600 to 700 deg. C. by a gas

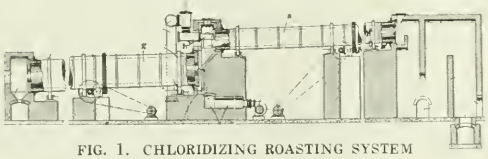

FIG. 1. CHLORIDIZING ROASTING SYSTEM

flame maintained at the nozzle h^3, at the lower end. Passage of the first kiln requires but a short time (from 30 to 40 minutes), during which the greater part of the metal to be recovered is chloridized. The heated mixture is discharged directly into the larger kiln *g*, where the same reaction is continued for a much longer time (3 to 8 hours), during which time elevated temperature and continuous agitation is maintained. This allows the final discharge to be almost completely converted. (1,245,634, Nov. 6, 1917.)

Sintering Blast Furnace Flue Dust.—A. J. BOYNTON of Lorain and A. E. SANDS of Akron, Ohio, have patented an improved method of sintering fines in pans having porous hearths. The usual process involves placing a layer of fines on a layer of crushed refractory protecting the grate bars. An igniter is then put into position above the pan, and an exhaust fan connected to the air box under the grate bars draws the products of combustion down through the mass of fines until the upper surface is burning. The igniter is then removed, the fan continues to draw air through the mass, thus gradually extending the combustion and agglomeration down through the entire mass. The results depend upon close control of the amount of combustible present in the fines, too much carbon resulting in the formation of liquid cinder which trickles down, plugging the interstices in grate bars and porous hearth, superheating the cake and apparatus, and causing non-uniform results. It is therefore necessary to consume much time in cooling the mass, thus delaying operation to such an extent that as much time is required to sinter the last 10 per cent of the material as is necessary for the first 90 per cent.

In the operation of the improved process the mixed and moistened material is spread on the porous hearth and ignited as usual. After combustion has proceeded until a hard crust has formed on top, the pan is rotated 90 deg. about air-exhaust trunions at the ends until the top surface is nearly vertical. The exhaust fan is kept running continuously, until sintering is completed; any cinder or slag which may liquidate out will trickle downward, now parallel to the porous hearth, and may be topped off by punching holes in the lower part of the cake. At the end of the process, the pan is further rotated, dropping the hot contents into a car beneath. (1,245,183, Nov. 6, 1917.)

Blast Roaster With Reciprocating Grates.—A. H. DERN of Salt Lake City and T. P. HOLT of Silver City, Utah (assignors to Holt-Christensen Process Co.), have

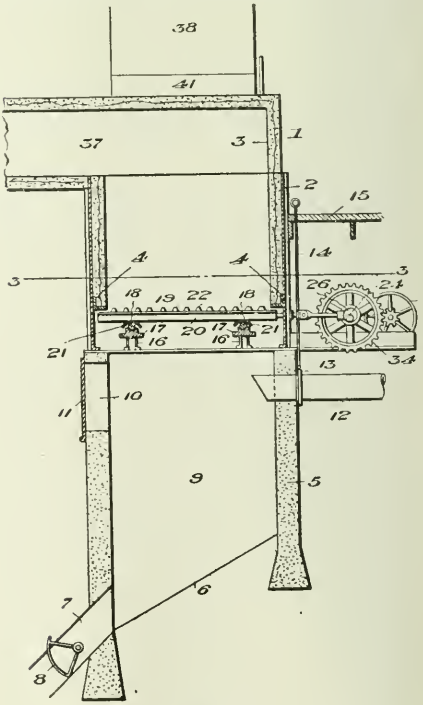

FIG. 2. HOLT-DERN BLAST ROASTER

patented improvements to ore roasters previously covered in Patents No. 1,113,961 and 2, Oct. 20, 1914. To afford a satisfactory draft without undue dust losses during charging, an inclosed rectangular roasting chamber communicates with a crosswise smoke flue (37),

and is charged through openings in the top. The grate is composed of a series of sections each made of a pair of longitudinal beams with crosswise teeth (22) at intervals on top. These may be driven independently by suitable mechanism (26) so that if the columnar roast settles more slowly in one part than in another, the first supporting grates may be operated a greater length of time. The body of the roaster rests directly upon a discharge bin (9), where the hot mass may remain for any desired period of time, which slow cooling is of advantage in chloridizing many ores. Air blast is introduced below the grates through the pipe (12), and the roasting is carried on in the manner described in the former patents. (1,251,189, Dec. 25, 1917.)

Metal Testing

Metal Sheet Testing.—The patent on the "Erichsen" metal sheet-testing machine, issued April 21, 1914 (No. 1,094,319) to ABRAHAM M. ERICHSEN of Christiania, Norway, has been reissued under date of Jan. 8, 1918 (No. 14,421). The machine was described in METALLURGICAL & CHEMICAL ENGINEERING for Dec. 15, 1916, p. 709.

Electric Furnaces

Two-phase Arc Furnace.—C. H. VOM BAUR of Douglaston, N. Y., has patented a two-phase arc furnace of the form illustrated in Fig. 3. Since in the two-phase, three-wire arrangement shown the central electrode carries $\sqrt{2}$ times the current in the lateral ones, the center of the furnace will be hotter, thus aiding in smelting down a fresh pile of ore and increasing the circulation in the molten bath. The side walls are dimensioned as shown so that overheating is avoided, all points receive approximately equal radiation. All electrodes are adjustable vertically; in addition the lateral electrodes, by means of spherical plug *F* and asbestos gaskets *G*, may be pointed toward any cold spot at the sides of the furnace. Flaming arcs are not desired, as being detrimental to the side walls and roof. The large area of slag-metal interface is of advantage in steel refining, and it is also claimed that the electrode arrangement gives a more steady current, fewer surges on the supply system and more uniform heat than a four-electrode, two-phase layout. (1,252,633; Jan. 8, 1918.)

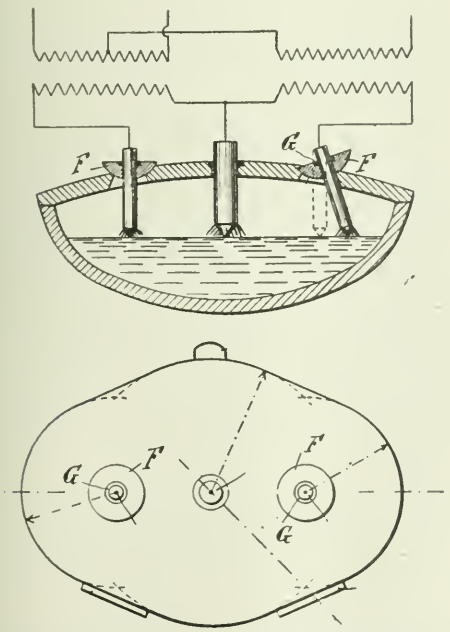

FIG. 3. PLAN AND ELEVATION OF TWO-PHASE ARC FURNACE

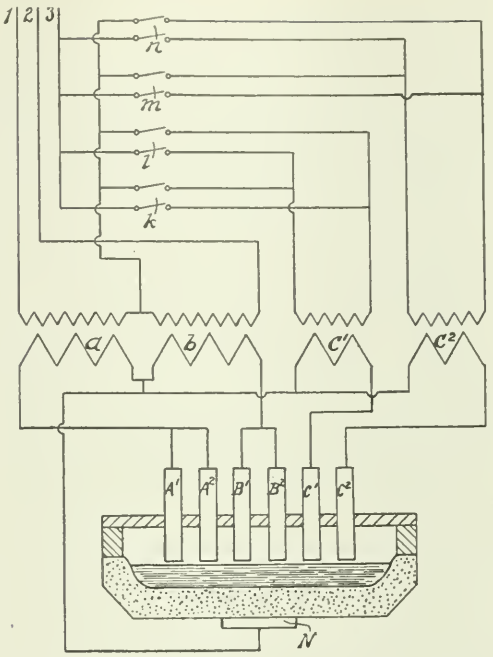

FIG. 4. WIRING DIAGRAM FOR HEAT CONTROL

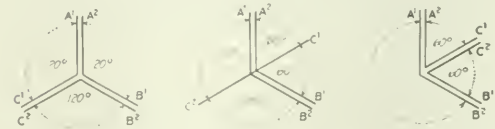
Polyphase Arc Furnaces.—J. L. DIXON of Detroit, Mich., points out that advantages would acrue to the operation of arc furnaces from an electric system whereby heat could be generated either by the flaming arc, or by conduction through the melt at the will of the operator, and without an unequal loading of the supply system. He illustrates a number of wiring diagrams whereby adjustable electrodes are connected to polyphase current supply, with a lower terminal *N* connected to a neutral point, and switches in circuit to alter the phase relations of the transformers. For instance, in Fig. 4, with switches *k* and *m* closed and *l* and *n* open, the currents occupy the positions shown in Fig. 5, and the only current flowing to the hearth is due to the difference in the secondary voltages. To



FIGS. 5, 6 AND 7. VARIOUS POSITIONS OF CURRENT

throw a large current to the hearth, open *k* and *n* and close *l* and *m;* this reverses transformer c^1, and the current is as in Fig. 6. Current as in Fig. 7 throws still larger currents to the hearth, and is had by reversing both transformers by changing the switches opposite to that of Fig. 5. In all cases the supply will not be unequally loaded provided each of the transformers *a* and *b* is supplying power equal to the total supplied by c^1 and c^2. (1,241,351; Sept. 25, 1917.)

Manufacture of Sodium Ferro-cyanide.—ALEXANDER R. TILLINGHAST of Solvay, N, Y., patents improvements in the process of making sodium ferrocyanide, and assigns the patent to the Semet-Solvay Co.

Sodium ferrocyanide may be formed by effecting the combination with carbonate of iron and an alkali of hydrocyanic acid gas as obtained from the gases evolved in the destructive distillation of coal. A difficulty experienced in such a process is the loss of cyanogen due to the formation, with ammonia of the gas, of ammonium ferrocyanide. The object of the present process is to obviate such loss and provide other improvements.

The ammonia constituent of the gas is first removed by absorption in water, and the gas containing the cyanogen is then scrubbed with water containing ferrous carbonate, or its equivalent, ferrous hydrate, in suspension, and also soda ash in solution in sufficient quantity to insure the alkalinity of the carbonate.

The liquor from the scrubber contains sodium ferrocyanide, which is in solution, soda ash in solution, probably all of which exists as bicarbonate of soda, a large excess of ferrous sulphide in the form of a black, insoluble sludge, and a considerable quantity of insoluble ammonium ferro-ferrocyanide due to the presence of unseparated ammonia in the gas.

In order to convert this insoluble ferrocyanide, and any other insoluble ferrocyanide that may be present, to the soluble form, milk of lime is added to the mixture, which is then boiled and allowed to settle.

After the desired reactions are effected the insoluble residue is allowed to settle out and the clear liquid is drawn off and concentrated to the point of crystallization, after which it is run into pans and the ferrocyanide allowed to crystallize out. (1,252,741, Jan, 8, 1918.)

In another patent (1,252,742, Jan. 8, 1918) Mr. Tillinghast describes a further improvement in recovering the sodium ferrocyanide already in solution. This patent relates chiefly to the treatment of the mother liquor remaining after a portion of the ferrocyanide has been crystallized out. The claim follows:

"In the process of producing sodium ferrocyanide from the cyanogen content of gas, the method of recovering from a mother liquor from which sodium ferrocyanide has been crystallized the residue of sodium ferrocyanide and caustic soda and sodium carbonate contained therein which consists in treating ferrous sulphate with the mother liquor whereby the sodium ferrocyanide is converted into ferrous ferrocyanide and the caustic soda and sodium carbonate form ferrous hydrate and ferrous carbonate forming a suspension of the ferrous ferrocyanide, ferrous hydrate and ferrous carbonate in a solution of soda ash and scrubbing cyanogen containing gas therewith in a repetition of the process, and finally treating the resulting solution with milk of lime to convert the insoluble ferrous ferrocyanide into sodium ferrocyanide.

Ohio engineering societies, comprising local and sections of national societies, held a meeting at Columbus on Jan. 29 and formed the Association of Ohio Technical Societies. The object is to bring about professional unity.

The Parker Rust-Proofing Process

AN INTERESTING rust-proofing process has been recently developed by the Parker Rust-Proof Company of America, of Detroit.

The effect of the Parker process is essentially a chemical one. The operation consists in taking metal iron or steel, thoroughly cleaning it by sand blast, pickle, or, in some cases, a soda bath. After this the cleaned metal is immersed in a chemical solution, where it remains a predetermined length of time, depending upon the nature of the metal and just what effect is to be obtained. After the metal has been removed from the solution, it is oiled with a special oil. The oil fixes the effect of the immersion and gives it a black mat finish. On articles that are to be painted the oil is not put on, but the metal is left just as it comes from the chemical bath.

According to a patent issued to Walter I. Oeschger and assigned to the Parker Co. (1,254,263, Jan. 22, 1918), the bath consists of a 1½ per cent solution of acid meta-phosphate of tungsten, molybdenum or any of the metals of the third, fourth or fifth groups. (According to G. S. Newth's "Manual of Chemical Analysis").

The acid meta-phosphate of most general application is made by placing a quantity of iron oxide, preferably black iron scale (Fe_3O_4) in a pot with sufficient phosphoric acid to form a soft paste. The iron oxide is preferabaly powdered in advance. An amount of water equal to the acid is added to keep the mass from caking, after which heat is applied and the material is stirred until a dry granular mass is obtained, which is then powdered. If desired, heat may be applied to the oxide and acid before water is added. To obtain the phosphates of the other metals, their oxides or carbonates may be similarly treated. The patent states that the bath is preferably kept at the boiling point when the articles are being immersed.

It has been found that the mixing of about 2 per cent of strontium acid meta-phosphate with the iron compound above described gives a much more uniform and harder surface when high carbon steels are treated. Practically the same good result is attained by using the same percentage of molybdenum or tungsten acid meta-phosphates instead of the strontium acid meta-phosphate in combination with the iron compound.

According to another patent (1,254,624, Jan. 22, 1918) issued to the above and also assigned to the Parker Co., the same results may be obtained by first heating the iron or steel articles to about 600 deg. F., and then subjecting them to fumes made by heating the acid meta-phosphates to a sufficient temperature. In this case the articles may be treated right in the furnace.

The tanks used in the wet process are steel with special lining and steam-heating coils attached to the side of the tank. Such an arrangement causes a constant agitation throughout the solution. Experience has taught that the best results are obtainable by a tank built up in this way. Tanks of this type are necessary to rust-proof at a low cost.

The company states that all forms of iron or steel can be processed. The finest kind of dental needles are

being treated and in the same tank large structural steel pieces, many parts more than 20 ft. long. Machined parts, castings, pressings, forgings are all handled in a similar way and the effect of the process is likewise similar in all cases. Machined parts sometimes do not require cleaning, and they are immersed at once. Smaller parts are pickled or sandblasted in a tumbling barrel, which cuts down the cost of cleaning.

The natural finish resulting from the process is a steel gray, which, when oiled, becomes a soft mat black. The surface of the Parker processed metal is stated to be exceptionally well adapted for enameling, since there is a very fine microscopic etching which helps to bind the enamel. If at any time the enamel should crack and expose a part of the rust-proofed steel, there would be no rusting set in and consequently no peeling off of the enamel.

The rust-proofed metal does not withstand every test imaginable. For instance, it will not withstand acids such as hydrochloric, muriatic, acetic, sulphuric. Again, it will not stand up against constant attack from chemical fumes, although it resists intermittent attacks. It will prevent corrosion when exposed to atmospheric attack and also in a good many cases to other extreme tests where acids are not used. Sterilizing solutions do not affect the process.

The company is operating a plant in Detroit with a capacity of 200 tons of metal a day. Plans are under way for establishing similar plants in New York, Chicago, Philadelphia, Pittsburgh, Boston and St. Louis. Licenses are issued by the company to operate under the process. It is claimed by the company that the process is 90 per cent cheaper than the original method used in England.

American Clay for Graphite Crucibles

THE manufacture of plumbago crucibles has been greatly affected by the present war. The two important ingredients in these crucibles are graphite and plastic clay. Graphite being a lubricant, is difficult to bond and requires a clay of high plasticity and adhesiveness with a high drying and heat shrinkage.

As pointed out by Mr. McNaughton of the Joseph Dixon Crucible Co. last fall in his paper before the American Institute of Metals on the crucible situation, all of the clay for crucible purposes and 95 per cent of the plumbago was imported. The clay used came almost exclusively from Klingenberg, Germany. Shortly after the war started Germany prohibited the exportation of this clay, and while crucible manufacturers had about a year's normal supply on hand they found that the demand for crucibles was rapidly increasing and their supply would last them a much shorter time.

The crucible makers hence warned their customers that the quality of crucibles made from domestic clays would be for some time an unknown quantity until sufficient service tests had been made.

Laboratories have been called upon for testing possible clays, and several clays which give promise have been found. It is usually two or three months, however, by the time a crucible is made, using this clay, and thoroughly tested out.

One interesting clay which has been produced is the so-called K-10 synthetic clay, developed at the Kraus Research Laboratories in New York and originally marketed by Chevalier & Tully of Baltimore, Md., but now handled by the Johns-Manville Co., who plan to market it on a large scale.

This clay is produced by making extractions from various clays, etc., which are so combined as to produce a fine-grained, highly plastic refractory mass having excellent bonding power. The shape of the grains must be such that the clay when moistened and dried will have high mechanical strength. Modulus of rupture tests made on this and other clays follow:

	Modulus of Rupture Lb. per Sq. In.	
	Raw	Mixed with 80% Non-Plastic Material
K-10	552	518
Klingenberg	374	381
Mississippi	507	168
H. & W.	310	67
Illinois	156	212

The following qualities are considered requisite for a good crucible clay: plasticity, adhesiveness, raw strength, density at low temperature, chemical balance, resistance to metals in fusion, high melting point, high shrinkage on drying, high shrinkage on heating and low coefficient of expansion.

Personal

Messrs. JOHN ALLINGHAM and N. H. BEATON have opened offices at 523-525 Lissner Building, Los Angeles, as assayers and chemists under the firm name of Allingham & Beaton. They expect to specialize in flotation tests. Mr. Allingham has recently been connected with the Humboldt Smelter, Humboldt, Ariz., as metallurgist. Mr. Beaton is a mining engineer and operated for several years in Canada and Mexico. He is at present manager of the Mining Department of the California Commercial Service, Los Angeles.

Dr. SAMUEL AVERY, chancellor of the University of Nebraska since 1909, has gone to Washington to serve as assistant chairman of the chemistry committee of the National Research Council, affiliated with the Council of National Defense. Dr. M. T. Bogert is chairman of the committee.

Dr. F. E. CARRUTH, formerly connected with the chemical division of the North Carolina Experiment Station, has become associated with the Schaefer Alkaloid Works, Maywood, N. J.

Prof. G. H. CLEVENGER has resigned as research professor of metallurgy at Stanford University and is now engaged in directing co-operative experimental work which is being done by the United States Bureau of Mines, Netherlands East Indies Government, Research Corporation of New York and others.

Lieut. A. W. DAVISON has been transferred from Washington to Niagara Falls, N. Y., where he is supervising chemical plant construction and experimental operation at the Oldbury Electrochemical Company.

Lieut. ELLERY K. FILES of the Gas Defense Service has been transferred from Washington to be instructor at the National Army camp at Yaphank, L. I.

Prof. D. M. FOLSOM of the department of mineralogy of Stanford University has been appointed by Mark L. Requa to be fuel oil administrator for the western states. His jurisdiction will cover Idaho, Montana, Utah, Arizona, New Mexico, Nevada, Oregon, Washington, California and Alaska.

Mr. PAUL W. FRYE, secretary and treasurer of the Laboratory Supply Company, Columbus, Ohio, has been made manager also, following the retirement from the company of Mr. Robert C. Schroth, Jr., former president and manager.

Mr. CLARENCE FULLER, manager of the Republic distillery at Curtis Bay, Md., has taken charge of the reopening of the distillery of Clark Brothers, Peoria, Ill., recently acquired, which will be devoted to the manufacture of denatured alcohol.

Dr. FRANK AUSTIN GOOCH, professor of chemistry and director of the Kent Chemical Laboratory of Yale University, will retire at the end of the present year. Professor Gooch will be succeeded by Professor Bertram Borden Boltwood, since 1910 professor of radiochemistry.

M. HENRI JEQUIER, metallurgist of the Société Minière et Metallurgique de Penarroya, and Dr. AUGUSTE HOLLARD, consulting engineer, are on a metallurgical visit to this country. The Penarroya company, which has its headquarters in Paris, and mines and works in Spain, is the largest smelter and refiner of lead in Europe.

Dr. YOGORO KATO, professor at the Tokyo College of Technology and Director of the Nakamura Chemical Research Institute in Tokyo, attended the recent annual meeting of the American Institute of Mining Engineers in New York. Dr. Kato expects to be in this country about two months on a professional visit.

Mr. H. W. KNOWLES of the New York office of the Cutler-Hammer Mfg. Co., has been transferred permanently to Washington for the period of the war. Mr. Knowles entered the service of the Cutler-Hammer Mfg. Co. shortly after graduating from Cornell University in 1912. He spent nearly five years in the shop, engineering department and sales department at Milwaukee. Since May of last year he has been connected with their New York district office, Hudson Terminal Building. The Washington Cutler-Hammer branch will have its headquarters at the Bradford, corner 18th and K streets, telephone Main 8426.

Mr. A. G. MCGREGOR of Warren, Ariz., and Mr. WILLIAM WRAITH, vice-president of the Andes Copper Mining Company, left New York City early in February for Chile, South America, where they will visit the site of the Andes Copper Mining Company's future reduction plants at Potrerillos. Mr. McGregor also expects to visit the smelter of the Cerro de Pasco Copper Corporation in Peru before his return to the United States, where he will supervise alterations and additions to their present equipment. Messrs. Wraith and McGregor expect to remain about three months.

Obituary

Mr. F. W. MATTHIESSEN, one of the pioneers in the zinc industry in this country, passed away at his home in La Salle, Ill., on Feb. 11. He was born in Germany in 1835 and was a graduate of the Freiberg School of Mines, where he formed his friendship with Edward C. Hegeler, both coming to this country together in 1856.

Their first enterprise in this country was an attempt to produce zinc from a silicate ore near Bethlehem, Pa. They were successful technically, but the company which had previously been working on it lacked funds to go on. They then went West to Missouri and made some successful experiments in smelting zinc ore, but political conditions interfered with commercial development, hence they went to Wisconsin and from there back to La Salle, Ill., where zinc smelting was definitely established by them. In 1871 the firm of Matthiessen & Hegeler was incorporated, and in 1881 a sulphuric acid plant was added. The firm became famous for its advanced metallurgical practice.

Mr. Matthiessen was for ten years mayor of La Salle and was a member of the American Institute of Mining Engineers. He was also principal owner of the Western Clock Co., makers of "Big Ben" clocks.

Mr. AUGUSTE MATHEZ, well-known mining engineer, passed away at his home in Denver, Col., on Feb. 4, Mr. Mathez was a graduate of the Columbia School of Mines and had extensive experience all over the world in the examination of properties, including China, Australia and South America. He was located for many years in Gilpin County, Colo., and was a well-known figure there.

Book Reviews

THE TECHNICAL ANALYSIS OF BRASS AND NON-FERROUS ALLOYS. By *W. B. Price* and *R. K. Meade.* Second Ed., 12 mo. (13 x 19 cm.), 376 pages, 25 cuts. Price, $3.00. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited.

The introductory chapter on Engineering Alloys is fragmentary and contains some questionable statements. The rest of the book is good. Thirty pages are given to describing apparatus for electrolytic analysis. The determinations of aluminium, antimony, arsenic, bismuth, cadmium, copper, iron, lead, magnesium, manganese, nickel and cobalt, phosphorus, silicon, sulphur, tin and zinc are discussed thoroughly, while those of chromium, vanadium and titanium are considered when occurring in bronzes. A unique and valuable chapter concerns the analysis and control of plating solutions for deposition of brass, zinc, copper, silver, gold and nickel. It is an eminently useful and practical treatise, full of personal experiences and advice from the quite competent authors.

* * *

PRINCIPLES OF QUANTITATIVE ANALYSIS. By *Walter C. Blasdale.* Second Ed. Duodecimo (12 x 18 cm.), 402 pages, 70 cuts. Price, $2.50 net. New York: D. Van Nostrand Company.

This is not the usual laboratory handbook, nor is it a mere copy of Ostwald's "Grundlagen der analytischen Chemie." It is an adaptation of the latter to the laboratory training of a professional analytical chemist. It is about one-quarter directions what to do and three-quarters explanation of the why and wherefore, as derived from the principles of physical chemistry. A limited number of analyses are described, usually rather briefly, and chosen rather for their suitability to illustrate principles than for their commercial importance. The book and its method are stamped strongly with the personality (and the personal views) of the author, and unquestionably his students, working under and with him while using the book, will get fine insight into quantitative analysis. Any other wide-awake instructor, using the book and supplementing it by copious drafts upon his own personal energy, will also achieve similar results.

* * *

THEORY AND CALCULATION OF ELECTRIC CIRCUITS. By *Charles Proteus Steinmetz.* 362 pages, with illustrations. Price, $3.00. New York: McGraw-Hill Book Co., Inc.

This with its companion volume, "Theory and Calculations of Electrical Apparatus," may be considered as continuations, revisions or enlargements of his well-known book published about 20 years ago on "Theory and Calculation of Alternating Current Phenomena." To include the most necessary structural elements of our knowledge of electrical engineering the whole subject matter of the older volume is now issued in greatly enlarged form in the two present volumes and a third on "Alternating Current Phenomena," which together form a set of books which it will be well for all engineers of the advanced class to familiarize themselves with. Much of the present volume, being written in an easily understood style, is also of interest and of great value to those who have only an elementary knowledge of the science and application of electricity.

The author's masterly knowledge of the subject gives one confidence in his statement of facts, many of which are highly interesting; and his past and well-known success in the application of this knowledge to practice gives one confidence in his interesting opinions. One therefore feels safe to accept his unorthodox and somewhat novel classification and treatment of the subject. When the subject demands it the mathematical treatment is given, but involved mathematics is the exception rather than the rule.

From the standpoint of the electrochemist, of the 18 chapters parts of the first two on conducton are the most

interesting. His classification of conductors is based on the nature and properties of the conduction, and on this basis he classifies conductors under metallic, electrolytic, pyroelectric and electronic, thereby including such conduction as in the arc, in vacuum, discharges in gases, carbon, metallic silicon, boron, metallic oxides, magnetite, Nernst filaments, sulphides, silicates (glass), salts, etc. His own exhaustive researches with some of these conductors, like magnetite, tend to make his statements authoritative. By comparing the curves showing the relations between the volts and amperes he is enabled to make a better classification than when based on resistance alone.

The other sections are on magnetism, wave forms of currents, the instability of circuits, reactance, constant potential, constant current transformating, constant potential series operation, load balance of polyphase systems, circuits with distributed leakage, and oscillating currents, many of which subjects are often of interest also to the electrochemical engineer who has to deal with large quantities of electric power.

The high standing of the author as both an able scientist and a practical engineer, and the general recognition of his abilities, gives this book a stamp of authority; and his originality, logical reasoning, and independence of thought free from the bias of orthodoxy add interest to his books.

* * *

THEORY AND CALCULATIONS OF ELECTRICAL APPARATUS. By *Charles Proteus Steinmetz.* 480 pages, with illustrations. Price, $4.00. New York: McGraw-Hill Book Co., Inc.

The relation of this volume to its companion on "Theory and Calculation of Electric Circuits" and to the author's former "Theory and Calculations of Alternating Current Phenomena" are explained in the review of the former, above, and need not be repeated here.

In the present volume the author discusses the most important characteristics of electrical apparatus including not only those in use but also many that may attain industrial importance with changes in industrial conditions. As an illustration he cites the time when small cheaply developed water powers will be united into one system, controlled from the central receiving station, in which case an entirely different type of generating station will have to be developed.

By "electrical apparatus" the author limits himself almost entirely to alternating-current motors though some space is devoted also to a.c. generators and to allied apparatus like rotary converters, frequency changers, rotary rectifiers, etc. With the exception of a short chapter on unipolar machines, and short references to several old types of series arc light machines, direct-current generators and motors are not included, and those that are briefly referred to are treated as alternating-current generators with rotary rectifiers. Nor is the ordinary static transformer included, except briefly as a special case of the rotary transformer. It would have been more explicit therefore to have limited the title to alternating-current rotary machines.

The treatment of the subject is directed to those who are already familiar with such machines and their characteristics and therefore supplements the more usual descriptive treatises. While the treatment in some cases is mathematical in character, by far the greater part of the book is descriptive and discursive text freely illustrated with many diagrammatic drawings and curves. While intended for the more advanced student and designer, there are many parts of the text which are instructive and interesting reading for those of lesser attainments also.

The recognized ability of the author and his long experience in the application of the higher scientific studies to the requirements of industrial practice, give the book an authoritative character.

To the electrochemist who is concerned with alternating-current machnery for power purposes the points of interest are the discussions of the characteristics, properties and behavior of such machinery, which will aid him in a better choice for specific conditions, as for instance when many small water powers are to be combined into one centrally controlled plant.

Current Market Reports

The Iron and Steel Market

The railroads had 15 days of extremely favorable weather, Feb. 6 to 20, inclusive, this being followed by weather only moderately favorable. As great progress as could possibly be expected has been made in clearing congestion on the roads, and a large quantity of loaded freight that was blocking yards and sidings has been moved forward to destination. Naturally the railroads addressed themselves to this task first, and not much has thus far occurred by way of returning empties, so that car supplies at blast furnaces and mills have increased very slightly, and shipments have been in corresponding proportion. As the major portion of the congestion has now been cleared, expectations are entertained that there will be a continued and important improvement in the supply of empties, with increasing shipments all along the line.

In 1917 such restriction in steel output as occurred was due to lack of pig iron, the restriction in pig iron being due to insufficient movement of coke and coking coal. While at times steel mill operations were interfered with by one influence or another, they were able to make up losses and produce as much steel as there was pig iron to make. In December the shortage of cars at steel mills became such that the mills were not able to ship as much as they were producing, and finished steel began to accumulate in considerable tonnage. In January this condition was accentuated, and stocks became such that production had to be curtailed to the rate at which steel could be shipped. From that time to date the governing restrictive influence has been the ability of the railroads to move steel. With the Garfield holidays, which closed steel mills and not blast furnaces, pig iron began to accumulate, and January as a whole showed a smaller proportion than normal of steel ingot production to pig iron production. Steel ingots were produced in January at the rate of about 28,600,000 tons per annum, pig iron production being at the rate of about 28,750,000 tons, whereas in 1917 the outputs had been approximately 42,200,000 tons of ingots and 38,600,000 tons of pig iron.

With the loosening up of traffic conditions in February a great deal of coke that was stalled en route was moved forward to blast furnaces, and even though shipments of coke did not increase materially many furnaces received a great deal more coke than was currently needed. Blast furnace operations underwent a sharp increase, whereas there was little increase in production of finished steel, and the result was a further accumulation of pig iron, also some accumulation of steel in intermediate forms, which may have reached considerable proportions.

Shipments of finished steel products in January averaged about 55 per cent of the mill capacity, which is fully 35,000,000 gross tons a year of finished rolled steel, nearly if not quite 3,000,000 tons a month, and February shipments have not been at much heavier rate, probably exceeding 60 per cent only slightly.

At the beginning of March, traditionally one of the two months of the year in which record outputs are made, the other, of course, being October, the iron and steel industry finds itself with improving traffic conditions, but still with no situation that can promise a record production. Physical conditions at the mills are, however, such that shipments can be increased as rapidly as the railroads furnish additional transportation, no matter how rapid that increase may be. There are large stocks of finished steel at mill awaiting shipment, and there is accumulated material all along the line, in the form of billets, ingots and pig iron.

The effect upon the market of any large increase in steel shipments is problematical. There is no assurance that ordinary commercial users of steel, not connected with the war, will be able to use steel in the greatly increased quantities that would be available if the mills were able to operate and ship at capacity. At an outside estimate the steel shipments since the first of the year have represented 60 per cent of the capacity, about two-thirds of this being war steel of all descriptions, including steel for the Government and for its Allies and steel for those who have contracts with these governments, not more than one-third being

ordinary commercial steel, entirely dissociated from the war. There are very few cases, indeed, in which the shipments of war steel have not been adequate. As a rule the steel mills have been able to supply war steel as rapidly as it could possibly be used. In many cases the shipments are not up to the original schedules compiled, but the utilization of this steel in shipyards, shell factories, etc., has likewise been behind schedule. In the circumstances it seems improbable that under the most favorable conditions there will be occasion to speed up the shipment of war steel by more than a small proportion, say from the recent proportion of 40 per cent of capacity to 50 per cent or possibly 55 per cent. At 100 per cent operation of the steel mills the supply of commercial steel would then be 45 or 50 per cent, against not over 20 per cent in the past two months. It is quite improbable that any such consumption of commercial steel could occur. Of course it is likewise improbable that the steel mills will be able to operate at 100 per cent in the near future, but it is interesting to put the problem in this way.

The comparison is particularly to the point in view of the fact that Washington is making a fresh effort to develop a system for the curtailment of unessential consumption of steel. Washington has addressed itself to this matter a number of times in the past, but after thinking of "pleasure automobiles" (which the automobile producers much prefer to call "passenger automobiles") has been unable to proceed farther. In the steel trade efforts to curtail artificially the unessential consumption of steel are regarded as unnecessary, for as a matter of fact many steel makers are concerned lest demand shall fall short of supply in the next few months. Undoubtedly steel is scarce, but the degree of scarcity is a slight one by comparison with the degree to which shipments of commercial or "unessential" steel have been reduced.

When on Dec. 29 it was announced by authority of the President that the set prices for iron and steel would be continued for revision by March 31, it was commonly thought that the Pomerene iron and steel price fixing bill would pass Congress, quite possibly by the end of January. The latest information is that no such bill will be pressed for the time being, if ever. Government price revision, therefore, if it comes at all, will be under the same principles as hitherto. The market shows distinct possibilities of declining under the set prices, as to some commodities at least, and it is quite possible that Washington may be disposed to let Nature take her course.

Chemical Market

Coal Tar Products.—There was not a great deal of activity in this situation since the last writing, although trading in general was of improved tone. The delays entailed by chaotic shipping conditions continue to be a disturbing factor. Plants in some localities are also greatly hampered by the scarcity of coal. Several of the important items are scarce and prices are higher, which to an extent is due to the added requirements of the Government in the manufacture of necessities required in the prosecution of the war.

Benzol.—Slightly more business was closed on contract over the next few months, but there continues to be some hesitancy on the part of consumers to close over the entire year because of the uncertain price position.

Phenol.—There continues to be but small quantities offered, with prices slightly higher. The Government has contracted for the entire output of some producers.

Toluol.—There is practically none of this material available on the open market. From time to time a few drums are available, but the Government is releasing but little and only in case a real necessity is apparent.

Naphthalene has been more active of late than for some time heretofore. The demand has materially increased, but offerings are light, with prices higher.

Aniline Oil has been quiet, but prices are fairly firm, due to the scarcity of acids.

Beta Naphthol.—There is a fair volume of business passing in technical grade, but the other grades are not in heavy demand; prices are unchanged.

Benzaldehyde.—The toluol situation tends to restrict production and higher prices are expected, with only a few producers offering.

Para Nitraniline.—A fairly active business is passing, but the production is heavy and prices are unchanged.

Benzoate of Soda.—There has been a decrease in the consuming demand, with prices slightly lower.

Saccharine continues weak, with offerings heavy, but it is slightly firmer than a few weeks ago.

Para Amido Phenol is slightly firmer, due to an increased demand, but it is possible to do a fairly low figure on material quantities.

H. Acid has not been particularly active of late, but the production is not heavy and prices are well maintained.

Heavy Chemicals.—Trading in products under this classification during the past two weeks has been rather restricted except for special products in light supply and difficult to obtain. The export trade has been further hampered by the presidential proclamation placing all products on the embargo list and requiring licenses for foreign shipments. In addition all imports are now subject to Governmental supervision.

Caustic Soda.—Further declines have occurred in this product and in certain positions caustic has sold under the 5c. point. There has been practically no demand from consumers, the small amount of trading noted being for the account of dealers. January shipments from works were reported to have been small, notwithstanding the fact that cars have been loaded heavy; in some cases it is reported that cars have been loaded in excess of 80,000 lb. Consequently January bills of lading have commanded a premium since the first of the month. This has been the only position that has sold at a high figure. February-June has been available as low as 4.75c. A new production of some 500 tons monthly of ash and caustic is announced by a new company in Texas.

Soda Ash.—The market, in contrast to caustic, has held well and trading has been somewhat more active. Barrels have generally commanded substantial premiums, as seemingly export licenses are being granted. Dense ash is offered more liberally, but supplies are not abundant by any means. Generally ash at out-of-town points has been available on more favorable terms than at New York.

Bichromate of Soda.—This product has been more active than any of the heavy chemical items since we last reported. A pronounced scarcity of prompt material and a quiet but insistent demand has forced values skyward. However, the product is classified as one of a highly speculative character and the trade is rather inclined to remain away from it unless there is a genuine demand. Sales occurred at 25c. and 25½c. At the moment of writing the situation is a trifle easier.

Calcium Carbide.—The production is still much below the demand and sales are occurring at unthought-of prices. The demand from South America is still persistent, and sales of various sizes have been recorded at prices ranging from 12½c. to 15c., crated in drums. Some uncrated material has been sold at 12c. The Canadian producers have been quoting 8c. f.o.b., but no actual material has been available at the figure.

Zinc Oxide.—There is also a greater demand for this product than the producers can satisfy and considerable speculation is noted. The XX Horsehead brand has sold at prices ranging from 13c. to 15c. and even at these figures there is not a great deal of material available.

Sulphuric Acid.—The continued scarcity of tank cars has retarded the movement to a noticeable degree, and as a consequence acid has backed up upon the producers, with the result that the plants probably have more material on hand than they have had for many months. Of course the bulk of this is held for the account of the Government, but there have been numerous offers of 66-deg. brimstone acid in tanks at prices ranging from $40 to $45, f.o.b. works, according to amount and shipment. Considerable acid for export has sold at $90, f.a.s. New York, drums included. Sixty-degree acid has been offered in the South at $20 per ton, sellers' tanks, sellers' works, sellers' option.

Copper Sulphate.—Resale lots have been eliminated to a certain degree and this, coupled with a restricted production, has tended to increased firmness. Nichols brand has been offered rather sparingly and sellers have generally

held to 9½, less 1 per cent. Outside brands have been offered from 9c. to 9¼c.

Formaldehyde.—The difficulty in securing wood alcohol as a result of the Government assuming control of the industry has created a firmer tone and there is much bullish talk. Sales have occurred at prices ranging from 19¾c. up to 21c.

Glycerin.—After a prolonged period of inactivity there has been business passing in dynamite at prices ranging from 63½c. to 64½c. A number of cars of soap lye have changed hands at 46c. and 46½c., basis 80 per cent loose at New York. Offers in the West have been reported at lower figures, but owing to shipping difficulties have not found buyers.

Sodium Sulphide.—Lack of shipping facilities has retarded the movement and some spot lots have been available at lower prices. Shipments from works, however, have held well and the market is approximately 4c., f.o.b., for the 60/62 fused material.

Nitrite of Soda.—Spot lots have become rather scarce and sellers are now invariably holding for 35c. as a minimum trading level. The production has not been on a very elaborate scale of late and stocks are not abundant at any point.

Nitrate of Soda.—So far on account of the Government purchase of 100,000 tons of nitrate for direct distribution to the farmers two cargoes have arrived at southern points —one at Charleston and one at Savannah, totaling in all 13,000 tons. It is reported that the demand for this material has been much in excess of the amount available and the farmers have been eager purchasers at $3.75 per 100 lb., f.o.b. cars, cash in advance. This situation has naturally tended to depress the outside market, and there has been very little nitrate moving. Importers have been quoting $4.50 for prompt and future shipments at all ports, but resales have been reported at $4.30 at various points.

Acetic Anhydride.—The production is being taken over by the Government for the purpose of impregnating airplane wings, with the result that there is very little material available on the open market. Production is confined to comparatively few sources as heretofore.

Carbonate of Potash.—Offers are seemingly confined to the Japanese material and sellers ask from 95c. to $1.05.

Cellulose Acetate.—Production at the moment is confined to possibly four sources, and these makers are turning their entire product over to the airplane service of the army on the basis of $4.50 for an 8-oz. bottle.

Prussiates.—Considerable activity has been noted in yellow prussiate of potash and some 10 tons changed hands at prices ranging from $1.22½ to $1.25. At the moment sellers hold to $1.25 to $1.27½. Prussiate of soda has been firm at prices ranging from 37½ to 38½.

Non-Ferrous Metal Market

Monday, Feb. 25.—The interesting features during the past two weeks were the advance in lead and the continued scarcity of tin. There is nothing new in copper and zinc.

Copper—The Boston News Bureau states that the total production of fifteen large companies was less in January, 1918, than in January, 1917. This decrease is expected to continue for a short time, but during the latter part of the year substantial gains should be made. Copper prices remain the same, as fixed by the Government.

Tin—There is hardly any spot market for tin, as none is for sale, but futures are being purchased to a considerable extent, with April Straits commanding 74½c., May 72 to 73c. and June 72 to 72½c. The situation as to shipments is no better, but American authorities are making every effort to have stocks released in London.

Lead—The trust price of lead was advanced to 7.00c. on Feb. 11. Independents are asking 7⅛c. The market is quiet.

Spelter—There is nothing new. Prime Western is very dull at 7¾c. St. Louis and 7⅞c. New York.

Tungsten—Sales of wolframite have been made in considerable quantity at $20.00 for future shipment of off grade material up to $24.00 for high grade spot.

Manganese Ore—There is a good demand and a premium has been paid for foreign ore. The nominal quotation is $1.20 per unit, basis 48 per cent.

Chrome—High prices have been asked for high grade chrome ore, with the nominal quotation at 1.50 for 45 per cent material at the Pacific Coast.

Other Metals

Aluminium, lb.	.36–.38

INDUSTRIAL

Financial, Construction and Manufacturers' News

New Companies

THE AMERICAN ALLOY & CHEMICAL CORPORATION, Los Angeles, Cal. Capital, $1,000,000. To manufacture chemicals and allied specialties. Incorporators: J. L. Boyle, G. A. Green, G. H. Beesemeyler, F. L. Riley, B. J. Quinn, and J. L. Stevens.

THE ANACONDA LEAD & ZINC COMPANY, Dover, Del. Capital, $100,000. To engage in a general mining and milling of lead and zinc. Incorporators: L. B. Phillips, and J. B. Bailey, Dover.

THE ATLAS DRAWN STEEL CORPORATION, Dunkirk, N. Y. Active capital, $275,000. To manufacture various drawn steel products. Incorporators: A. H. Hunter, A. F. Dohn, and H. E. Webster, Buffalo.

THE AURORA SILVER MINES CORPORATION, New York. Capital, $1,000,000. To engage in a general mining business. Incorporators: S. B. Howard, George V. Reilly, and A. W. Britton, 65 Cedar Street.

THE BANKERS LEAD & ZINC COMPANY, Oklohama City, Okla. Capital, $250,000. To mine for lead and zinc. Incorporators: G. A. Morris, W. A. McAtee, and H. E. Brouillard, Wapanucka, Okla.

THE BEST MINING COMPANY, Shawnee, Okla. Capital, $200,000. To mine for lead and zinc. Incorporators: S. H. Lester, M. J. McLaughlin, and H. B. Callahan.

THE BONE-DRY LIME CORPORATION, Jamestown, N. Y. Capital, $100,000. To manufacture commercial fertilizer, etc. Incorporators: C. Lamberton, Franklin, Pa.; J. C. Dick, Utica; and A. Davis, Jamestown, N. Y.

THE BUCKNER PROCESS COMPANY, Worcester, Mass. Capital, $20,000. To manufacture chemicals, petroleum products, and allied specialties. Harry L. Buckner, Wollaston, is the principal incorporator.

A. M. CASTEL & COMPANY, Dover, Del. Capital, $1,500,000. To manufacture tools and iron and steel products.

THE CHLORINE PRODUCTS COMPANY, New York. Capital, $100,000. To manufacture chemicals and kindred specialties. Incorporators: S. B. Howard, G. V. Reilly, and A. W. Britton, 65 Cedar Street.

THE CLAREMONT PAPER COMPANY, Bellows Falls, Vt. Capital, $1,500,000. To manufacture paper, etc. Incorporators: J. N. Harvey, Harold E. Whitney and H. C. Fenton, Brattleboro.

THE CLARK COUNTY OIL & GAS COMPANY, Montgomery, Ala. Capital, $100,000. To manufacture gas and produce and refine oil. Incorporators: J. C. McCarquadale, F. H. Grande, and C. T. McCarquadale.

THE CRESCENT COLOR & CHEMICAL WORKS, Plainfield, N. J. Capital, $25,000. To manufacture colors and chemicals, etc. Incorporators: A. and J. and Walter Alexander, all of New York.

THE CRESCENT LEAD & ZINC COMPANY, Miami, Okla. Capital, $250,000. To operate lead and zinc properties. Incorporators: J. A. Utterback, O. E. and W. A. Doty, Newkirk.

THE D-B-L PRODUCTS CORPORATION, New York. Capital, $150,000. To manufacture celluloid products. Incorporators: A. W. Burke, C. H. Louis, and I. L. Ernst, 151 West Eighty-sixth Street.

THE DIAMOND CHEMICAL COMPANY, Utica, N. Y. Nominal capital, $7,000. To manufacture chemicals. Incorporators: F. A. Hill and H. J. Willett, Utica.

THE ELLSWORTH MINING COMPANY, Miami, Okla. Capital, $150,000. To engage in a general lead and zinc mining business. Incoroprators: Lloyd Weber, J. Wise Brown, Tulsa, and A. B. Elisworth, Joplin, Mo.

THE FLORENCE PIPE FOUNDRY & MACHINE COMPANY, Philadelphia, Pa. Capital, $1,000,000. To operate a foundry and engage in the manufacture of special machinery. Incorporators: Charles R. Wood, Spencer P. Hazard, Edwin J. Lane, Philadelphia; Thomas L. Morton, Palmyra, N. J.

THE FORGE PRODUCTS CORPORATION, New York. Capital, $160,000. To manufacture high speed steel products. Incorporators: A. E. Moore, F. H. Butehorn, and A. F. McCabe.

THE FOUR STATES MINING COMPANY, Idabel, Okla. Capital, $50,000. To mine for lead and zinc. D. B. Strawn is the principal incorporator.

THE GALCONDA MINING COMPANY, Ardmore, Okla. Capital, $15,000. To mine for lead and zinc. Incorporators: John M. Imrie, E. E. Chivers, and O. C. Lasher.

THE GIVENS MINING COMPANY, Athens, Ga. Capital, $64,000. To mine for gold. Incorporators: E. L., A. J. Haughey, and Theodore Brough, Athens.

R. H. GREEFF & COMPANY, New York. Capital, $200,000. To manufacture chemicals and allied products. Incorporators: W. N. Barnum, F. E. Dixon, and R. H. Greeff, New York.

THE GREENFIELD LEAD & ZINC COMPANY, Greenfield, Okla. To mine for lead and zinc. Incorporators: J. E. Ross, J. C. Collier, and J. W. Baker, Greenfield.

THE HANCOCK FOUNDRY & MACHINE COMPANY, New Cumberland, W. Va. Capital, $25,000. To operate a local steel plant.

THE INTERNATIONAL IRON & STEEL COMPANY, Augusta, Me. Capital, $250,000. To manufacture iron and steel products. E. M. Leavitt, Augusta, is president and treasurer.

THE INYO CHEMICAL COMPANY, Reno, Nev. Capital, $1,000 000. To manufacture chemicals and chemical compounds. Incorporators: H. W. Carr, Saginaw, Mich.; J. N. Morris, and W. M. Gardner, Reno.

JENNINGS & COMPANY, Boston, Mass. Capital, $90 000. To manufacture dyestuffs, etc. Incorporators: F. W. Bourne, Waldo Farrar, and C. W. Jennings, Boston.

THE KNOX DRAWN STEEL COMPANY, Pittsburgh, Pa. Nominal capital, $5,000. To manufacture drawn steel products. J. G. Bassett is the principal incorporator.

LAWLESS BROTHERS PAPER MILLS, Rochester, N. Y. Capital, $150,000. To manufacture paper and paper products. Incorporators: M. D., M. J. and D. J. Lawless, Rochester.

H. S. LENT, INC., New York. Capital, $25,000. To manufacture cordage and twine from hemp fibre, etc. Incorporators: W. Coemen, F. E. Fehr, and R. S. Strahan, 44 West Ninth Street.

THE LIBERTY STEEL & FOUNDRIES COMPANY, New York. Capital, $1,500,000. To manufacture iron and steel products, etc.

THE LORANE MINING & ROYALTY COMPANY, Miami, Okla. Capital, $40,000. To mine for lead and zinc. Incorporators: Ray Thompson, C. C. Moses, J. T. Dewberry and J. T. Gephart.

THE LYON SOAP PRODUCTS COMPANY, New York. Capital, $25 000. To manufacture soaps and soap products. Incorporators: A. DeGobi J. E. McCullough, and L. S. Furman, 356 East Twelfth Street.

THE MANUFACTURERS PRODUCTS COMPANY, New York. Capital, $100,000. To manufacture chemicals, leather product, etc. Incorporators: H. C. Neuberger, H. Burlingham, and C. M. Chapman, 2 Rector Street.

THE MOGUL MINING COMPANY, Oklahoma City, Okla. Capital, $250,000. To mine for lead and zinc. Incorporators: F. E. Sheets, T. F. Tate, and W. L. Buck.

THE MONTANA CHROME MINING COMPANY, Philadelphia, Pa. Capital, $1,000,000. To engage in a general mining business. Incorporators: F. R. Hansell, Philadelphia; J. V. Pinm and S. C. Seymour, Camden, N. J.

THE MORE PRODUCTS COMPANY, Los Angeles, Cal. Capital, $10,000. To manufacture fertilizers from kelp, etc. Incorporators: Frank Martin, George Cunningham, Z. Jones, and E. W. Tunsgate, Los Angeles, and H. M. Henning, Santa Barbara.

THE NEW HAVEN IRON & STEEL COMPANY, New Haven Conn. Nominal capital, $9,000. To manufacture iron and steel products. Incorporators: William Alderman, Charles Merberg, M. A. and A. N. Alderman, New Haven.

THE NOEQUA CHEMICAL COMPANY, Philadelphia, Pa. Capital, $450,000. To engage in the manufacture of chemicals and allied products.

THE ORETON COMPANY, Wilmington, Del. Capital, $100,000. To manufacture iron and steel products.

THE ORGANIC PRODUCTS & COLOR COMPANY, Elizabeth, N. J. Capital, $50,000. To engage in the manufacture of dyestuffs and allied products. Incorporators: Hugo Helburn, Seymour M. Hermann, New York; and Charles B. Rasenberger, Brooklyn.

THE PARKER TIRE & RUBBER COMPANY, Dover, Del. Capital, $750,000. To manufacture automobile tires and other rubber goods. Incorporators: M. L. Horty and K. E. Longfield, Wilmington.

THE PEARSE ENGINEERING COMPANY, Ltd., Dover, Del. Capital, $100,000. To engage as chemical engineers. Incorporators: J. G. Gray, M. B. F. Hawkins, S. S. Adams, Jr., Wilmington.

THE POLLOCK-BURT PAPER COMPANY, Dallas, Tex. Capital, $10,000. To manufacture paper and paper products. Incorporators: Lawrence S. Pollock, S. Dreyfuss, and William J. Burt.

ASHMEAD F. PRINGLE, Inc., Charleston, S. C. Capital, $200,000. To engage in the manufacture of fertilizers. Incorporators: A. F., E. H. Pringle, and Frank E. Barron, Charleston.

THE QUENEIDA GRAPHITE CORPORATION, Birmingham, Ala. Capital, $3,000,000. To engage in the production of graphite. Incorporators: J. F. B. Baugh, Birmingham; J. D. Baker and J. P. Murray, Philadelphia, Pa.

RENAUD & COMPANY, Inc., New York. Capital, $25,000. To engage in a general mining business. Incorporators: G. Renaud J. S. Galland, and D. J. Dowling, 20 Stuyvesant Place, State Island.

THE SALICYLATE PRODUCTS MANUFACTURING COMPANY, Newark, N. J. Capital, $25,000. To manufacture chemicals and allied products. Incorporators: A. C. Ullman, Charles D. Wagler and William P. Murphy, all of Newark.

THE SEMINOLE CHEMICAL COMPANY, New York. Capital, $100,000. To manufacture chemicals. Incorporators: M. Suesskind and I. J. Joseph, 1421 Madison Avenue.

THE SEMINOLE VARNISH COMPANY, Tampa, Fla. Capital, $500,000. To manufacture varnishes, etc. Incorporators: Gustave Tuschell, 144 Lafayette Street, Tampa.

THE SMITHVILLE ORE CONCENTRATING COMPANY, Inc., New York. Capital, $70,000. To mine for ores of various kinds. Incorporators: K. L. Alexander, M. Anelli, and E. Powers, 15 Broad Street, New York.

LEOPOLD SONN & BROTHER, New York Capital, $30,000. To manufacture paper, paper boxes, and other paper specialties Incorporators: S. H. and F. and L. Sonn, 132 Mulberry Street.

THE STEEL SPECIALTY CORPORATION, Pawtucket, R. I. Capital, $100,000. To manufacture steel products. Incorporators: Fred A. Sweet, Walter A. Briggs and George E. Thurber.

THE TANTEX LEATHER CORPORATION, Newark, N. J. Capital, $100,000. To engage in the manufacture of leather, leather products, etc. Incorporators: Charles L. Mason, Harold Bouton and F. J. Israel, Newark.

THE UNION STEEL PRODUCTS COMPANY, New York. Capital, $100,000. To engage in the manufacture of steel products. Incorporators: R. Tally and I. and M. Gordon, 700 West One Hundred and Eightieth Street.

THE UNITED STATES AND BRAZIL EXPORT COMPANY, Inc., New York. Capital, $10,000. To deal in chemicals and dyestuffs Incorporators: James W. McGovern and Joseph Gambaro.

THE UNIVERSAL IRON PRODUCTS COMPANY, Wilmington, Del. Capital, $1,200,000. To manufacture steel rails, iron bars, culverts, etc Incorporators: M. Gehrman, William F. O'Keefe, and E. E. Wright Wilmington.

THE VALLEY MINING COMPANY, Miami, Okla. Capital, $150,000. To engage in a general mining business for the production of lead, zinc, etc. Incorporators: R. T. Price, J. A. Stokes and H. Russell

THE WESTERN MAGNESIA PRODUCTS CORPORATION, New York. Capital, $10,000. To manufacture magnesia products. Incorporators: V. W. Thorpe, O. J. Heig and I. V. Weisdrob, 71 Broadway.

THE D. L. WILKOFF STEEL COMPANY, Pittsburgh, Pa. Capital, $50,000. To manufacture steel products. H. T. Feinberg is the principal incorporator

THE WILMINGTON SUGAR REFINING COMPANY, Dover, Del. Capital, $15,000,000. To manufacture and refine sugar and molasses. Incorporators: Adolph and Earl Segal, and Thomas B. Hall, Philadelphia, Pa.

THE WOODBRIDGE CERAMIC CORPORATION, Woodbridge, N. J. Capital, $30,000. To manufacture fire brick, etc. Incorporators: N. Peter Jensen, P. P. Svhendorf and William H. Prall, Woodbridge.

Construction and Operation

Alabama

ASHLAND. — The Crystalline Flake Graphite Company is making rapid progress in the construction of its new mill for the concentration of graphite and it is anticipated that operations will be inaugurated about March 15.

Arizona

BISBEE.—The Dos Cabezos Gold Ridge Mining Company, with properties in Cochise County, is planning for the immediate construction of a new mill to have a capacity of 100 tons. The company has been doing extensive development work at its mines, and it is estimated that the ore reserve is sufficient to supply the proposed new mill for about ten years.

PEARCE.—The Middlemarch Mining Company, about seven miles west of Pearce, has completed the construction of a new flotation plant, and will inaugurate operations at an early date.

PRESCOTT.—Plans are being considered by the Consolidated Arizona Smelting Company for the immediate enlargement of its smelter, the plant, when completed, to have a capacity of 2,500,000 pounds of copper per month.

PRESCOTT.—The Locey Pabst Gold Mines Company has completed the installation of new electrical equipment at its properties, and is planning for the immediate construction of a new mill to have a capacity of 100 tons daily.

SAN XAVIER.—The Mineral Hill Consolidated Mining Company is planning for extensive development work at its properties in the San Xavier district, Pima County. The main shaft has been sunk to a depth of 500 feet, the ore that is being blocked out assaying 4 per cent copper. A new duplex electrical pump, capable of handling 250 gallons per minute is now being placed, the power to be supplied by a 75-horsepower semi-Diesel Y-type engine and 50-kw. generator.

Arkansas

CONWAY.—Fire, on February 10, originating in the lint room of the plant of the Conway Cotton Oil & Gin Company, caused a loss of approximately $20,000.

FORT SMITH.—The Fort Smith Smelter Company, which is now operating three blocks of its four-block smelter at South Fort Smith, is planning to place the fourth block of the plant in operation at an early date.

LITTLE ROCK.—The Southern Paint Manufacturing Company, manufacturer of a special roofing paint, is planning for the removal of its plant and offices from Camden to Little Rock. The company controls extensive lignite mines at Corcoran Spur, and through a special retorting process, produces a high grade carbon from the lignite, which carbon is used as a base for the company's roofing paint, iron paint and darker colored house paints.

California

FRESNO.—The California Products Company has awarded a contract for the construction of a new reinforced-concrete drier at its plant, which was recently destroyed by fire. The new drier is estimated to cost $60,000. The company is contemplating the construction of a new acid plant, concrete storage towers, and new elevator system. The Cahill-Vensano Company, San Francisco, is the contractor.

LOS ANGELES.—The Chemical Production Company is making rapid progress in the construction of a large new plant at Owens Lake, to be devoted to the manufacture of soda ash.

LOS ANGELES.—The Stauffer Chemical Company, manufacturer of chemicals and kindred products, is building a new plant on a site comprising about fifteen acres, recently acquired, to be devoted to the production of hydrochloric acid. The new works are estimated to cost about $100,000.

LOS ANGELES.—The Western Calcium Chloride Syndicate has completed the equipment of a large new plant for the manufacture of calcium chloride.

SAN DIEGO.—The Steele Packing Company is considering the lease of a large site on the tidelands at the foot of Jupiter street, to provide for the construction of a large fish packing and reduction plant. The entire works are estimated to cost about $70,000.

RANDSBURG.—The Yellow Aster Mining Company has commenced the operation of its old mill, which has been idle for some time, pending the completion of the new plant now in course of construction. Development work at the mine has uncovered ore buried by the great slide of 1914, and in the new plant, which will be double the capacity of the former, the coarse product will be eliminated by screening, and the fine ore, containing practically all the gold, will be fed directly into the stamps. Plans are under consideration by the company for the mining of its large bodies of low-grade ore by steam shovels or a cableway excavator, and is considering the installation of a set of ball-mills to replace the stamp mill.

SAN FRANCISCO.—Fire recently partially destroyed the plant of the Eagle Tanning Company, Vermont street and San Bruno avenue, with loss estimated at $50,000.

PORTOLA.—The Anaconda Copper Company is said to have completed arrangements for taking over the interest of the Plumas Copper Company in the Walker Mine, about 25 miles from Portola, for a consideration of $500,000. For the past few months the mine has been developed under the direction of the International Copper Company, and concentrate from the flotation plant has been shipped to the Tooele smelter. The flotation plant has a daily capacity of 160 tons.

WASHINGTON.—The Washington Asbestos Company is planning to inaugurate operations in its mill at an early date. The company has been developing its asbestos claims all through the winter.

AUBURN.—The Pacific Coast Mines Company has recently acquired title to the Dutch, Sweeney, and App mines, and is preparing plans for extensive development work. The company is considering the immediate construction of a large new mill to have a capacity of about 700 tons daily. Experiments have also been perfected for a special treatment for the sulphide ore.

YERINGTON.—The Kennedy Copper Company is planning extensive development work at its mines in the Buckskin Mountain, near Yerington, and is considering plans for the construction of a new flotation plant in the early spring.

Colorado

EUREKA.—Rapid progress is being made by the Sunnyside Mines Company in the construction of a new crusher plant and 500-ton flotation works at its mines.

PUEBLO.—The Colorado Fuel & Iron Company is planning to inaugurate operations at an early date in its new by-product coke ovens at the Minnequa works, now in course of construction. The plant consists of two batteries of sixty ovens each, designed for sixteen-hour coke, to have a capacity of approximately 70,000 tons of coal a month, with a coke production of 46,000 tons. The new plant, which will comprise the ovens, benzol works, coal washer, and other structures is being erected by the H. Koppers Company, Pittsburgh, Pa., and is estimated to cost about $4,000,000.

DENVER.—Plans have been perfected for the organization of the American Mineral Oil Company, which has acquired about 1400 acres of shale fields and is planning for the construction of a large plant for the production of oil. H. M. Roeschlaub, Denver, heads the company.

Connecticut

STAMFORD.—The American Synthetic Color Company has filed plans for the construction of its proposed new two-story brick and concrete addition, about 30x130 feet, on Sunnyside avenue. Contract has been awarded to Harold A. Parsons, Bank street, Stamford, at a price of $12,000.

Delaware

WILMINGTON.—The E. I. du Pont de-Nemours Company has awarded a contract for the construction of a new plant for the manufacture of powder and high explosives at Sattes, W. Va., to cost about $10,000,000. The Thompson-Starrett Company, 49 Wall street, New York, is the contractor. It is said that the company has made arrangements with the War Department for the erection of two plants at Charleston, W. Va., and Nashville, Tenn., respectively, to have a capacity of about 1,000,000 pounds of smokeless powder daily, combined.

WILMINGTON.—The Ball Grain Powder Company, recently incorporated, will build a new one-story shell-loading plant at Miller road and Thirty-second street. Pans for the structure have been prepared.

WILMINGTON.—Fire on February 16, at the local recovery plant of the du Pont Powder Company, seriously damaged one of the buildings.

WILMINGTON.—The plant of the Baldt Steel Company, which is engaged on work for the Government, was damaged to the extent of about $150,000 by fire, on February 16.

Georgia

ATLANTA.—Fire, on February 12, partially destroyed the plant of the Southern Chemical Products Company, following an explosion.

Idaho

WALLACE.—Rapid progress is being made by the Spokane Metals Recovery Company in the construction of a new 200-ton plant on Nine Mile Creek, about three miles from Wallace, and it is expected to inaugurate operations at an early date. The equipment includes a flotation system and tables, the water of the creek and its mineral content being conveyed to the plant by a 500-foot flume. C. L. Hewett is president and manager of the company.

Illinois

CHICAGO.—The American Tractor Company, South Michigan avenue, will build a new tractor plant at Peoria, to include two foundry buildings, assembling works, machine shop, main manufacturing building, power plant, and auxiliary structure. Plans for the work are being prepared. The entire plant is estimated to cost about $150,000.

CHICAGO.—The Twin Tube & Rubber Company, South Michigan avenue, has filed plans for the construction of a new one-story and basement works. Contract for the structure, which will be about 40x40 feet, has been awarded.

CHICAGO.—The Indian Refining Company has recently acquired property on Western avenue, between the right of way of the Atchison, Topeka & Santa Fe Railroad and the Illinois and Michigan Canal, for a consideration of about $20,000, as a site for the construction of a new compounding and distributing plant.

GALENA.—The Blewett Mining Company, recently incorporated with a capital of $100,000, is planning for extensive development work on its zinc ore properties about half a mile from Galena. Work has been started on a new shaft, and the company is considering plans for the immediate construction of a mill building.

Indiana

WHITING.—The Sinclair Oil Company is making favorable progress in the construction of its new local refinery. The company has made announcement that the laying of a pipe line from the mid-continent field to Whiting has been practically completed. This pipe line has been in course of construction for about two years, and is the second of its kind to cross the Mississippi River, the Standard Oil Company having laid the first one.

GREENCASTLE.—The Indiana Portland Cement Company is having plans prepared for a new cement works to cost about $1,000,000. The plant will include a main manufacturing building, cement mill, machine shop, and auxiliary structures. Adam Beck is president.

INDIANA HARBOR.—Plans have been filed and contract awarded by the Standard Forgings Company for the construction of a new addition to its plant to cost about $15,000.

Iowa

MUSCATINE.—Plans are being prepared by the Continental Serum Company for the construction of a new plant to replace its laboratories recently destroyed by fire. The new works will be located on the site of the former plant in Park Place, and are estimated to cost $50,000. Dr. S. S. Houk is head of the company.

OAKVILLE.—The Hall Air Lock Company has completed arrangements for the leasing of a large foundry building at Granville, Ill., for the manufacture of its products.

Kansas

FREDONIA.—The Fredonia Oil & Gas Company, the Sunshine Oil & Gas Company and other large oil interests, are said to be considering a site in Fredonia for the location of a large new oil refinery.

Maryland

BALTIMORE. — The Continental Can Company, Keyser Building, has had plans prepared for the construction of a new two-story addition, about 35x100 feet, to its works at Orangeville.

BALTIMORE.—Plans are being prepared by the H. E. Crook Company, Inc., Light street, for the reconstruction of its shipbuilding plant at Locust Point recently partially destroyed by fire with loss estimated at $50,000. Howard E. Crook is president.

HAVRE DE GRACE.—The Atlas Powder Company has awarded a contract to the Ley Construction Company, Pittsburgh, Pa., for the erection of a large new chemical manufacturing plant, comprising from thirty-five to forty concrete buildings, including power house, administration buildings and manufacturing units, together with housing and tracking facilities. The entire works are estimated to cost approximately $5,000,000.

LUKE.—The West Virginia Pulp & Paper Company has completed plans and specifications for the proposed new plant which it will erect for the Government to be devoted to the manufacture of industrial alcohol and other chemicals from pulp and paper mill waste. The new works are estimated to cost about $3,000,000.

Massachusetts

CAMBRIDGE.—Fire recently partially destroyed the plant of the American Hard Rubber Company, Potter, Pinney and Ninth streets, with loss estimated at $30,000.

FITCHBURG.—The core department and main foundry building of the Fitchburg Foundry Company were recently damaged by fire, with loss estimated at about $5000. M. J. Perault is manager.

BOSTON.—The works of the Plant Leather Company, 113-17 North street, were recently partially destroyed by fire, with loss estimated at approximately $30,000. The company was engaged on Government contracts.

Michigan

GRAND RAPIDS.—The St. Paul Pioneer Press & Dispatch Company is making rapid progress in extensive improvements in its local paper manufacturing plant, to increase the capacity by approximately 40 per cent. Included in the work is the construction of a new power house, the installation of new generating and manufacturing devices and a new 750 horsepower electric generator. Improvements have been made in the grinder room, and a new cylindrical barker has been installed.

SAGINAW.—The Northwestern Glass Company is planning to inaugurate operations in its new local plant about March 15. About 200 hands will be employed for initial operations. W. G. Edmonds is secretary and treasurer.

Minnesota

MINNEAPOLIS.—The Minneapolis Steel & Machinery Company has taken out a building permit for the construction of a new factory building at East Twenty-ninth street and Snelling avenue, to cost about $28,000

Mississippi

LAUREL.—The plant of the Laurel Oil & Fertilizer Company was partially destroyed by fire recently with loss estimated at about $55,000. It is said the damaged sections will be immediately rebuilt.

Missouri

ST. LOUIS.—The American Manufacturing Company, 1026 South Eleventh street, has had plans prepared for the construction of a new one-story brick and concrete machine shop, about 60x70 feet, at its works at East St. Louis, Ill., to cost about $30,000.

ST. LOUIS.—Fire recently damaged buildings Nos. 9 and 13 at the plant of the Mallinckrodt Chemical Works, manufacturers of chemicals and allied products.

ST. LOUIS.—The St. Louis Malleable Castings Company, Conduit avenue, is considering the construction of a new plant to cost about $50,000.

Montana

HAMILTON.—The Ravalli County Sugar Company, which was recently organized to take over the interests of the Montana-Utah Sugar Company, has postponed the construction of its proposed new sugar factory which is estimated to cost about $750,000, due to the scarcity of labor and materials in this section. V. L. Arnold is local manager.

Nevada

ROCHESTER.—The United States Smelting, Refining & Mining Company has completed arrangements for the taking over and operation of the mines of the Nenzel Crown Point Mining Company. The United States company is planning for the construction of a new mill at the properties and extensive development work.

TONOPAH.—The Belmont Wagner Mining Company is making rapid progress in the construction of a new 300-ton mill at its mines, and it is anticipated that the new plant will be in operation by March 15.

New Jersey

JERSEY CITY.—The George H. Segal Company, 139 Logan street, manufacturer of chemicals, is planning for the reconstruction of its plant recently destroyed by fire.

JERSEY CITY.—The Zibell Damp Resisting Paint Company, 273 Water street, New York, has acquired local property consisting of six city lots on Culver avenue and four lots adjoining on Fisk street, as a site for the construction of a large new plant.

HOBOKEN.—Robert Mayer & Company, Clinton street, manufacturer lithographic inks, etc., has acquired the property of the Prana Carbonic Syphon Company, about 50x100 feet, at Eleventh and Adams streets, to be used as an extension to its works.

NEWARK.—The Verona Chemical Company, Verona and Riverside avenues, has taken out a building permit for the construction of a new one-story brick extension to its plant.

KEARNY.—The Blast Furnace Products Corporation, recently incorporated in Delaware, has acquired the plant formerly occupied by the New Jersey Zinc Company on the Hackensack River, adjoining the Newark Plank Road, Kearney, comprising about 12½ acres, for a consideration said to be about $350,000. The property has a frontage of 930 feet on the river, and is about 915 feet deep, and it is said that the company will use it for the establishment of a new works.

RIDGEFIELD PARK.—The British-American Chemical Company, 52 Vanderbilt avenue, New York, is planning for the construction of new additions to its plant at the site of the Tennessee Copper Company, recently acquired.

PLAINFIELD.—The Niles-Bement-Pond Company, manufacturer of machine tools, is planning for the erection of two new plant buildings at its works to cost about $40,000. The company is also having plans prepared for its proposed new plant on the Kearny meadows near Kearny, on property recently purchased. The works will consist of a group of one and two-story buildings, comprising machine shops, riveting works, erecting shops, etc., and will cost about $2,000,000. The plant will be used for the manufacture of cranes industrial locomotives, and other specialties.

EDGEWOOD.—The United States Government has announced plans for the construction of a large plant for the manufacture of gas, to cost about $35,000,000

New Mexico

MOGOLLON.—The Socorro Mining & Milling Company is making rapid progress in the erection of its new mill, and it is anticipated that operations will be inaugurated around May 1.

New York

NEW YORK.—The Imperial Chemical Manufacturing Company, 135 West Twenty-third street, has leased property at 382 Lafayette street, to provide for increased capacity.

BROOKLYN.—Charles Pfizer & Company, 11 Bartlett street, manufacturers of chemicals, etc., have awarded a contract for alterations and improvements in its plant on Gerry street, near Harrison street, to cost $15,000.

BROOKLYN.—The National Lead Company is having plans prepared for the construction of a new five-story plant, about 95x210 feet, at Marshall, John and Gold streets. The new works are estimated to cost $250,000.

MECHANICVILLE.—Contract has been awarded to the Fuller Construction Company, New York, for the erection of the proposed new plant for the Government to be constructed near the plant of the West Virginia Pulp & Paper Company. The new works will be devoted to the manufacture of acetone, which is used in connection with varnish for the coating of aeroplane wings.

LOCKPORT.—The Upson Company, manufacturer of wall board, has acquired the plant of the St. Clair Paper Company, Capac, Mich., and is planning to dismantle and remove adjacent to its local plant. The consideration was $150,000. The addition will be used for the manufacture of a new fibre product, and will give employment to about 250 additional hands.

BUFFALO.—The Great American Chemical Company, manufacturer of chemicals and allied products, has taken out a building permit for the erection of a new factory building to be located at 284 South Park avenue, to cost about $9000.

North Carolina

GASTONIA.—Fire recently destroyed a portion of the plant of the Rhyne Roller Mill Company, East Gastonia, with loss estimated at $10,000.

LEXINGTON.—The Natural Chemical Products Company, recently incorporated with a capital of $350,000, has completed arrangements for the development of about 500 acres of feldspar deposits in Mitchell County. Contracts have been awarded for the necessary mining machinery and for the chemical equipment for the extraction of potash from the feldspar rock.

RALEIGH.—The Empire Steel Company is planning for the immediate construction of a large new steel plant to have an initial capacity of 100,000 tons. The works will comprise a blooming mill, bar mill, tube mill, and laboratories, with a 10,000 horsepower electric plant. For the present the company will specialize in the production of seamless tubes but are planning for a general steel and iron business. John S. Long is president.

Ohio

CLEVELAND.—The Monarch Brass Company, 1621 East Forty-fifth street, has awarded a contract for the construction of a new one-story foundry, about 90x100 feet, to cost $12,000.

CLEVELAND. — Contracts have been awarded by the Bowler Foundry Company, 1688 Columbus Road, for the construction of a new foundry building, about 75x200 feet, to cost $40,000. The company specializes in the production of iron castings.

SANDUSKY.—The Ohio Tread, Tire & Manufacturing Company, which recently established new offices in the Lawrence Building, is planning for the construction of a large new local plant.

TOLEDO.—The Rex Spray Company, manufacturer of arsenate of lead, recently suffered a loss of about $15,000 on buildings and $50,000 in machinery, etc., in connection with a fire at its plant.

YOUNGSTOWN.—The Sharon Steel Company, which recently took over the plant of the Youngstown Iron & Steel Company, has acquired the furnaces of the Iron & Steel Company, Lowellville, for a consideration said to be $3,000,000. The company is planning to increase its capital from $10,000,000 to $15,000,000, and is considering the construction of additional blast furnaces.

Oklahoma

PICHER.—The Producers' Mining Company is considering plans for the immediate construction of a new 300-ton concentrating plant on a 40-acre tract of lead and zinc properties recently acquired. L. V. Hlvick, Oklahoma City, is president.

TULSA.—The Republic Refining Company is planning for the construction of a new 2500-barrel oil refinery at Jennings. It is said that a pipe line will be laid from Jennings to the Cushing field by way of the Quay plant, which will serve the proposed refinery.

MIAMI.—The Federal Lead & Zinc Company has awarded a contract to Henry M. Martin, Miami, for the construction of a new 300-ton plant. The company has been doing extensive development work on two of its leases, one of 20 acres and another 40 acres, and the new plant will be located on a blocked-out site on the 20-acre lease. The estimated cost is $85,000.

Oregon

GRANTS PASS.—The Gold Hill Manganese Company, recently incorporated with a capital of $1,000,000, is planning for the developing of its four claims on Shan Creek, six miles from Rogue River, including the installation of crushers, jigs, water motor, stamp mill, saw mill, and auxiliary apparatus.

PORTLAND.—Fire recently destroyed the plate room at the plant of the Northwest Steel Company decreasing the operation of the works by about twenty-five per cent. The damage is estimated at about $35,000. The company will commence the rebuilding at once. J. R. Bowles is president.

Pennsylvania

GLENSHAW.—The Glenshaw Glass Company has commenced the reconstruction of its one-story plant, about 75x100 and 50x100 feet, respectively, recently destroyed by fire.

PHILADELPHIA.—The Philadelphia Paper Manufacturing Company has acquired property adjoining its plant on River road in the Manayunk section for a consideration of $25,000. It is said the new property will be used for extensions.

PHILADELPHIA. — The Nitrogenous Chemical Company is having plans prepared for the construction of a new one-story brick and concrete plant at Thirty-seventh and Tasker avenues, to be devoted to the manufacture of sulphuric acid.

PHILADELPHIA.—The United States Conditioning and Testing Company has completed its enlargement plans at its chemical laboratory, to provide for increased capacity.

HUNTINGTON.—The Aetna Explosives & Chemical Company is planning for the immediate construction of new additions to its plant at Mount Union for the manufacture of smokeless powder. The extensions are estimated to cost $500,000. The new plant will be especially adapted for the manufacture of dyes and chemicals after the close of the war.

PITTSBURGH.—Fire recently caused a loss of about $25,000 in the plant of the United States Glass Company, Winnebago street, South Side section, Factory A.

Texas

TOYAH.—The Toyah Texas Sulphur Company, recently incorporated with a capital of $350,000, is planning for the immediate development of about 600 acres for the production of sulphur. A large new plant will be erected. James C. Buchanon is president.

EL PASO.—The Kansas City Smelting & Refining Company has completed extensive improvements at its local plant at an estimated cost of about $1,000,000, including a new copper blast furnace, two new converters and new mechanical ore conveyor.

Utah

MARYSVALE.—The American Agricultural Potash Company has inaugurated operations in the second alunite potash mill of the Florence Mining & Milling Company, and two additional mills are now in course of construction.

SALT LAKE CITY.—The Standard Oil Shale Company is planning for the construction of a large new plant at Elko comprising a new refinery and a distillation retort with a daily capacity of about 100 tons. Professor Otto Stahlman is consulting engineer for the company.

FISH SPRINGS.—Daniel Livingston, J. A. Rich, and associates, have acquired the plant and properties of the Utah Mining Company, and are planning for the construction of a new concentrating plant.

Wisconsin

MILWAUKEE.—The George H. Smith Steel Casting Company has taken out a building permit for the erection of a new foundry and office building at Clinton street and Greenfield avenue, to cost $50,000.

ANTIGO.—Mayer Brothers, specializing in the manufacture of power hammers, have taken over the plant of the Kaukauna Machine Works, and have filed notice of a change in its corporate name to the Kaukauna Machine Works Company.

Canada

KIRKLAND, ONTARIO. — The Teck-Hughes Mining Company is making extensive improvements in its mill to increase the capacity and improve the recovery.

PORT MOODY, B. C.—The Aetna Steel Works are planning for the installation of a new six-ton electric smelter furnace.

PRINCETON, B. C.—The Canada Copper Company is planning for the immediate construction of a new 3000-ton concentrating plant. Power for the operation of the works will be furnished by the West Kootenay Power & Light Company, Trail, which will extend its electric transmission system to this plant.

ANYON, B. C.—The Granby Consolidated Mining, Smelting & Power Company, is making extensive improvements at its local copper mines, including the installation of new converters to increase the capacity from 75,000 to 85,000 tons per month. The company is also constructing by-product coke ovens at the plant to have a capacity of 350 tons of coke and 500 tons of coal daily. The work is estimated to cost $1,-500,000.

Trade Notes

GRASSELLI CHEMICAL EARNINGS. — The Grasselli Chemical Company reports that net earnings for the year 1917 of approximately $4,300,000, against $9,935,000 in 1916, $4,859,000 in 1915 and $1,680,000 in 1914. The stockholders have voted to approve the proposal to increase the stock to $50,000,000, of which $35,000,000 will be common and the remainder preferred.

GENERAL CHEMICAL EARNINGS.—The General Chemical Company saved a net profit last year of $7,671,151 from a gross return amounting to $14,694,686, after setting aside $1,800,000 for Government war taxes and making substantial reservations for insurance and depreciation. In 1916 the profit was $2,024,000 larger, although taxes then were much smaller. The surplus for 1917 after dividends had been paid was $4,320,-160, and the total surplus was $15,719,170, against $11,399,010 a year before.

ERICHSEN SHEET METAL TESTING MACHINE.—Herman A. Holz, 1 Madison Avenue, New York, owner of the American rights to the Erichsen patent, announces that the patent was reissued to Mr. Erichsen on Jan. 8, 1918 (No. 14,421).

MINERALS SEPARATION NORTH AMERICAN CORPORATION announce the removal of their San Francisco office and testing laboratory from the Merchants Exchange Building to 520 Battery Street, where they have established an ore-testing works.

THE ASBESTOS PROTECTED METAL CO. of Pittsburgh announces the removal of its Boston office to the State Mutual Building, to be in charge of Mr. William H. Cummings.

AMERICAN NAMES FOR AMERICAN DYES.—John Campbell & Co., 75 Hudson Street, New York, have issued a pamphlet on colors in which pertinent recommendations are made for the American dyestuff industry. The concluding part of the pamphlet says:

"Every American manufacturer of dyestuffs should give to his colors an appropriate name. We should get away from the habit of referring to American colors by foreign names. In a comparatively short time we have produced colors that are equal to, and in many instances better than, the so-called German standards. It is only a question of time when the fastest, rarest, and most intricate dyes will be produced in this country.

"Now, the American consumer will never willingly put himself in the position he occupied when the war shut off the supply of German colors. He realizes the necessity of having a dependable source of supply at home, and the only way this can be done is for the consumer of dyes to support the American dyestuffs manufacturer. No American mill man should use the German trade words for the names by which he has known colors in the past. To do so would be playing right into the hands of the German business propagandist. Therefore, let us be loyal to everything American, and among other things designate the American colors by their American names."

LOW-VISIBILITY PAINTS.—The latest issue of *Graphite*, the house-organ of the Jos. Dixon Crucible Co. of Jersey City, states that commercial ships are now also painted so that they blend with misty weather and with the horizon. The company manufactures natural and olive green silica-graphite paints for this purpose.

THE HOLCROFT & LANE CO., Detroit, Mich., which has built core and mold ovens for the H. M. Lane Co., also of Detroit, has changed its name to Holcroft & Co. They will continue as a purely contracting organization and have made arrangements with the H. M. Lane Company for their engineering, consulting and drafting work. The operations of the two companies, however, have been entirely divorced, and Holcroft & Company are now located at 555 Book Building, Detroit, Mich. The latter company also makes open-hearth and miscellaneous metallurgical furnaces.

DRIVER-HARRIS COMPANY, Harrison, N. J., on the night of Jan. 31, suffered a loss of fire of their insulated wire and electrical cord departments. These buildings have been completely destroyed. The company's business in production of resistance materials, castings, cold rolled strip, nickel sheet and other products is not interfered with.

NEW OFFICE FOR NATIONAL ANILINE.—A new office building at 21 Burling Slip, New York, will be occupied about May 1, 1918, by the National Aniline & Chemical Co., whose office at present is at 244 Madison Avenue. The new building, acquired through the Century Colors Corporation, one of the constituent companies of the National Aniline & Chemical Company, Inc., has long been known as the best equipped and most modern of dyestuffs headquarters anywhere outside of Germany. Prior to the war it was the headquarters for the distribution of dyes produced in Germany by Leopold Cassella & Company. But whereas during this period but four stories were used for office, laboratory, and clerical purposes, the National Company, together with the Century Colors Corporation, will occupy the entire ten floors for these purposes, in a thoroughly re-equipped building, with the entrance on Burling Slip. It is near the main offices of the General Chemical Company, the Barrett Manufacturing Company, the New Jersey Zinc Company, and other great chemical concerns.

FINE PLATINUM WIRE.—The Richardson Research Laboratory of Cleveland announces that it has succeeded in making a fine platinum wire to take the place of spider web for cross hairs in telescopes, etc. Platinum wire shipped to their customers recently is reported to be 0.000975 in. in diameter.

THE DURIRON CASTINGS COMPANY of Dayton, Ohio, manufacturers of Duriron, acid-alkali-rust-proof apparatus, announces the removal of its Chicago office to the Harris Trust Building, to continue in charge of Mr. George A. Cocup.

GOLDSCHMIDT COMPANIES COMBINE.—Announcement is made that the business of both the Goldschmidt Detinning Company and the Goldschmidt Thermit Company will hereafter be conducted by the "Metal and Thermit Corporation" with general offices at 120 Broadway, New York. These two concerns have been practically combined for the last two years and have occupied joint offices at the above address. The combination, which is controlled exclusively by Americans, has now been put in more permanent form as it is felt that this will tend towards greater efficiency and co-ordination of effort.

The detinning department of the Metal and Thermit Corporation will carry on one of the largest industries of its kind in the world, i. e., the recovering of tin from tin scrap. Approximately 4,000,000 tons of tin scrap is treated yearly by this department and the recovery approximates the equivalent of 2000 gross tons of metallic tin. The output of this branch of the corporation consists of pig tin of a quality equalling Straits tin, tetrachloride of tin and detinned billets, the latter being the iron scrap after the tin is removed.

In addition to its line of carbon-free metals and alloys, the company produces pure tungsten powder in very considerable quantity. It is also selling agent for the output of a large plant in the middle West producing 50 per cent electric furnace ferro-silicon.

The Thermit welding proces is used by many of the railroads in the United States and Canada for welding broken locomotive frames and other heavy sections. It is also used very extensively by the different steel mills for welding broken equipment, such as rolls, pinions, crank shafts, etc. The process is extensively employed for the welding of rails for trolley lines, the welding of broken sternposts and rudder frames of steamships.

The Metal and Thermit Corporation operates four different plants located respectively in Jersey City, Chrome, N. J., Wyandotte, Mich., and Chicago, Ind. The Chrome and East Chicago plants are devoted to the detinning industry; the Wyandotte plant to the production of liquid chlorine, and the Jersey City plant to the Thermit products, including welding materials, carbon-free metals and alloys and pure tungsten powder. The corporation operates branch offices and welding shops in Pittsburgh, Chicago, San Francisco and Toronto.

The following are the officers and directors: W. T. Graham, Edgar L. Marston, Daniel G. Reid, F. S. Wheeler, Huhert E. Rogers, F. H. Hirschland, E. L. Ballard, L. A. Welles, Charles F. Dane, Philipp Gensheimer, Fred W. Cohen.

Playing with Platinum Prices

THERE are some metals of such limited known distribution in the earth's surface that their economics are comparatively simple and easy of comprehension. Platinum is one of them. Produced for the major part in the Urals of Russia, and latterly to an important extent in Colombia, the metal is recovered only incidentally elsewhere. With the Russian supply curtailed, if not entirely cut off, the prospect for platinum in plenty is not alluring, and Colombian sources assume an aspect of greater importance.

The supply of platinum in the United States may fall short of demand; at least that is a fair inference from the order of the War Industries Board, which we publish elsewhere, commandeering platinum supplies in this country. Putting together the facts just stated, *viz.*, that we face a platinum shortage and that the only places from which we can get it in quantity are Russia and Colombia, it would seem to be fair business sagacity to offer an inducement for the production of platinum and its shipment to this country. At least we should not deliberately place any obstacles in the way.

For over a year the prices of platinum have been fairly stable at $103 @ $105 per ounce. We are informed, however, that the War Industries Board proposes to pay only $90 per ounce for the 20,000-oz. lot brought from Petrograd some months ago by Mr. Draper. Presumably if so inconsiderate a proposal is made in this instance, domestic dealers who have no alternative will fare no better. We may now frame a simple question: Under the conditions just outlined, how much platinum will the War Industries Board be likely to get? The answer seems equally simple: Just about the available stock now in the United States, *and no more.* And yet we face a shortage of platinum, and produce practically none of it in this country.

Within the period of the war it has been amply demonstrated that economic laws still work in the case of needed metals. The memory of the tungsten boom is still fresh in the minds of many. Tungsten was suddenly needed in large quantities. The price rose rapidly and became so attractive that people literally combed the hills of Boulder county, Colorado, getting a bucketfull of high-grade float in the course of a few days. A great deal of the mining was crude and much of the milling was wasteful; but we got tungsten, and the price stayed up until it attracted supplies from Burma and other foreign countries where the mineral was laboriously accumulated by natives. Even their simple wants could not be met by shipping tungsten to this country when the market was normal. It took a stimulus in the form of a high price to make them active producers. Supplies having been brought out plentifully, the price fell off and has remained down ever since. We commend the incident to the War Industries Board.

Post-Mortem Reports

METALLURGISTS are agreed, privately, that a public record of failures and negative results would be quite as beneficial to the profession as the more customary announcement of successes. For this reason we consider it important to publish in this issue an account of a careful but unsuccessful effort to treat sulphide copper ores with nitric acid. Mr. Westby is to be commended not only for a clear discussion of the chemistry of the method, but for a frank revelation of an unsuccessful attempt to supply a process which had gained considerable notoriety in the West and which was heralded as a solution of some of our metallurgical problems.

A striking point among the reasons for failure was the inability to make a complete recovery of the solvent —nitric acid. The commercial meaning of even a three per cent loss was painfully evident when costs were estimated. The results of ten tests with laboratory apparatus indicated an average nitric acid recovery of 90.5 per cent and an average copper extraction of 88.9 per cent. The former is distinctly poor and the latter not strikingly good. In large-scale tests the results were not nearly so good. Compared with roasting and leaching with sulphuric acid, the nitric acid process held no attractions in estimated profits, for under the most favorable assumptions of recovery of acid and copper the nitric acid process showed an estimated net profit of only $2.46 per ton as against $3.27 by roasting and leaching with sulphuric acid.

Iron and Steel Price-Fixing

THE iron and steel industry is quite accustomed to kaleidoscopic changes, and war brings its own sudden and great changes, so that it is not surprising that conditions in the steel industry are radically different from those that obtained six months and twelve months ago. A year ago steel prices were trending upwards very sharply indeed. To-day the question is whether the War Industries Board will seek lower prices for the next period, the present set prices having been, by the announcement of last December, extended to March 31. On an average, the present set prices are approximately at the same level as the market of one year ago. Price-setting simply eliminated the additional advances that occurred March to June inclusive of last year.

There are, in essence, two important changes that have occurred in the position of the War Industries Board which, with the President's approval, represents the government. The first change is really the absence of a change that was expected to occur. Last December, when the War Industries Board approved an extension of the set prices to March 31 of this year, the expectation was entertained that long before the new date had arrived the Pomerene or some other iron and steel price-fixing bill would have passed Congress. The authorities at Washington expected they would have some legal authority over iron and steel prices in general, of somewhat the same character as the authority that was given by the Lever act of August, 1917, with respect to "food, feed and fuel." The proposed legislation was dropped, however, partly, no doubt, because Congress has been so busy—in the Congressional sense —with other legislation that it could not consider iron and steel, but partly also, beyond question, because the iron and steel industry was found so ready to follow instructions or requests, no matter upon what authority they rested, that legal enactment did not seem necessary. Thus the War Industries Board to-day is without a legal authority that it was expected to possess by this time.

The other important change is that the tactical position of the government in this matter is altogether altered. During the months in which a voluntary agreement—the expression may be somewhat tautological but it is sanctioned by usage—was sought, the position of the steel makers was that government orders were accepted solely as a patriotic duty while ordinary commercial orders represented a much larger tonnage and much higher prices.

By legislation enacted before the war started, the government was empowered to fix "fair" prices upon any material it bought. For a time the view of the steel industry was that the government should go ahead and fix prices on its purchases, leaving the industry to fix its own prices on the steel sold to the general public. The latter represented by far the larger tonnage. President Wilson insisted this would not do, that there should be "one price for all." Finally he enunciated his views in a very clear and direct statement, July 12, which statement was received with much consternation and some criticism, but has since been tacitly accepted universally as a necessary and eminently proper rule of conduct.

Nine months ago the iron and steel market was still "going strong." With the government empowered to fix prices on the material it bought, and on nothing else, to propose that there should be one price for all seemed like proposing that the tail should wag the dog. Since then there has been a complete reversal. If the government were now to fix prices upon all material required for the war and leave producers to name prices themselves upon all other material the government would be fixing prices upon the bulk of the material, not upon a minor part. It has taken over the railroads, and it could go farther and take over bodily the petroleum industry, the motor car industry, and some others, leaving little steel consumed on the outside, when building operations for peace purchases have dwindled to insignificant proportions. Thus the War Industries Board is now so well fortified that apart from considerations of patriotism it is practically in control.

There is in fact no question of authority and no general divergence of opinion. The matter of iron and steel prices has become purely one of expediency, what is best for the country. On the one hand, the prices to be paid for pig iron or steel should not be exorbitant, whether it is the government, its Allies, or the general consuming public that is the buyer. On the other hand, prices should be such as to afford reasonable profits to the manufacturers, not to the few, but to the great majority, to all except those manifestly inefficient. The government elected to obtain a large part of its war chest by taxation, and elected furthermore to tax production rather than consumption. There must be profits to be taxed or the scheme falls to the ground.

Conditions have been such in recent months, with greatly restricted output and correspondingly mounting costs, and costs varying widely from week to week and from plant to plant, that it is a practical impossi-

bility at the moment to determine closely what is a fair price. Compared with some recent costs the present prices may be too low. By other comparisons they may appear too high. The industry hopes for better operations and steadier costs even in the next few weeks now that the season has changed. The wise course will probably be to let the present price structure stand without disturbance for a time at least.

The Crystal-Gazer

THE crystal-gazer who could read the past, present and future of the world by concentrating his attention upon a small silvered ball, has his scientific counterpart in the metallographist who cuts a few ounces of metal from the lining of a huge rifle, gazes at these fragments through his microscope, and proceeds to reconstruct the behavior of the sixty-ton bulk during and after the lightning flash of powder and shell. Who shall attempt to predict the limits to the metallographer's domain when some studies in the quiet of laboratory and library reveal the metal's travail during catastrophic explosions?

A most striking example of the efficacy of accurate observation and clear reasoning in the solution of the problems of industry is presented in a paper on "The Erosion of Guns" read at the New York meeting of the American Institute of Mining Engineers by that remarkable American, Henry M. Howe. We published a summary in our last issue, but for the entire article we bespeak the closest study. Even the non-metallurgical reader can admire this investigation for its sheer beauty, while the metallurgist will derive inspiration and courage in this evidence of the important work which is possible even with a moderate amount of instrumental equipment when reinforced with a large amount of intellectual resource.

Ammonia, Refrigeration and Munitions

A VERY serious need just now is that of ammonia. There is a demand for it by the government so great as to tax every possible source of supply, and the question may soon have to be met as to where the use of ammonia may be curtailed. The United States Government requirements for May, 1918, are three times, and for December, 1918, seven times its requirements for February of this year; but government nitrate-producing plants are under construction and it is hoped that they may be completed in time to avert any serious dislocation of industry.

The largest industrial use is for refrigeration. Of the 6,000,000 tons of ice annually used in New York City, for example, about one-half is artificial. Ten cities of the United States produce annually about 8,000,000 tons of artificial ice, and most of this is refrigeration by the ammonia process.

The United States Food Administration is taking the matter in hand and is urging with energy the harvesting of natural ice wherever possible, and hints and directions for doing this are sent broadcast. Ice-producing plants are urged to co-operate for the saving of ammonia and fuel, and such co-operating parties are urged to avoid legal complications or the infringement of anti-trust laws by conferring with local officials in this emergency. All refrigeration establishments are urged to stop losses of ammonia, to eliminate corroding factors from their circulating liquors, to return empty cylinders to supply firms and to harvest all the natural ice they can. Every coal-gas plant that consumes over 5000 tons of coal per year is urged to save its ammoniacal by-products. Parties contemplating the erection of new artificial ice plants have been addressed by the Food Administration through its Division of Chemicals, pointing out the pressing need of ammonia for munitions and its prospective shortage. They are urged to postpone such undertakings. Over a dozen booklets have been prepared and are distributed to municipalities on the safe and proper use of natural ice. Trading in ammonia, ammonium sulphate and ammoniacal liquors in quantity has been placed under license, and manufacturers are cautioned not to buy over 60 days' supply. Hoarding will be punished by cutting off the entire supply.

From the foregoing it will be observed that Mr. Charles W. Merrill, chief of the Division of Chemicals of the U. S. Food Administration, is not letting the grass grow under his feet.

The only trouble with substituting CO_2 and SO_2 for NH_3 in plants which are designed for the use of ammonia is that in the present state of the art it can't be done. The compression pressure required for ammonia is from 185 to 200 lb. per square inch. For carbon dioxide from 1000 to 1200 lb. is needed. It stands to reason that apparatus built to withstand 200 lb. will not endure 1200. The compression pressure required for sulphurous oxide is low, but the pump and refrigeration pipes must be made of brass or copper for obvious reasons. SO_2 does not behave well in iron and on the other hand NH_3 gets nervous in copper or brass. There does not seem to be any way available in the light of present knowledge to shift from ammonia to carbon dioxide or sulphurous oxide or any other gas in ammonia refrigeration apparatus. And considering the need of mechanics in the industry of war, new equipment is not available.

Large quantities of ammonium nitrate are used in domestic explosives. Under normal conditions, produced at an expense of 6 or 7 cents per pound, it is the cheapest explosive ingredient of blasting powder. With glycerine at 60 to 65 cents a pound, and almost impossible to get at that, the use of high explosives for this purpose is prevented and a heavy burden as well as a serious problem is placed upon the mining interests. The conversion of starch to glycerine is still very indefinite. It has not yet reached an economic stage.

There are certain economies proposed by Col. Walker that do not come under such close surveillance as those industries under observation of the Food Administration, and to these we not only call the attention of our readers but invite suggestions as to the best methods of carrying them out.

Old, exhausted, dry batteries are usually thrown away. This is a serious waste, as they still contain 80 per cent of their ammonium chloride and all of their manganese dioxide. If these were exchanged when new ones are purchased, instead of thrown away, an economy in charging and in the use of ammonia would be effected. Galvanizing works also are large users of ammonium chloride, and one has but to enter them to see waste in many instances. In the preparation of soldering fluids and fluxes the use of ammonium chloride should be discouraged as far as possible.

Readers' Views and Comments

Co-ordinating Production and Transportation

To the Editor of Metallurgical & Chemical Engineering

SIR:—There are indications on all sides that we are approaching an industrial and economic crisis. One of the most evident signs of this is the amount of criticism which is being showered on those in charge of Government activities, nearly all of which at present relate to the war. The attempts to blame these various inefficiencies on individuals are being made on all sides. It was only natural in this confusion that army officers and Government officials in general should be the first to receive the blow, for we have always held the theory that Government officials were far more inefficient than our business men.

The number of applications from private manufacturers for the help of "efficiency engineers," which has so largely increased lately, is indicative of a realization on the part of many of our manufacturers that their methods also are not what they should be. The people who are applying for help are, in many cases, no worse off as far as their methods are concerned than others who haven't yet discovered how badly they are doing their work. The whole subject seems to resolve itself into the fact that our business and industrial systems are not suited for times like these, when it is necessary to combine all our energies and exert our full driving power toward the achievement of one supreme object.

We should not be surprised that this is the case, for our economic theory has never contemplated teaming up all the industries of this country for one object, but has rather discouraged that idea and encouraged individual competition of the most strenuous kind. In other words, we are a nation of individualists who have never really seriously contemplated coöperation for the common good.

Past Training Unsuited to Present Needs

When this problem of coöperation is suddenly put up to us as it has been by the war, it is not surprising that our business men, trained in the individualistic school, should be entirely unfitted to solve the new problem. Moreover, it might be expected that the men who have been most successful in individualistic, competitive business, in which profit was the main aim, should be actually the ones least fitted to establish a scheme of business and production for the benefit of the community. This is a new problem to them, and one altogether outside of their experience.

It is to be granted that such business men may have individually great driving power, but this very excess of driving power in individuals or corporations is likely to make the confusion all the worse, unless a means of co-ordination is established which will keep the driving power of the individuals or corporations in proper balance.

It has become perfectly evident to all observers that the capacity of the nation for production of war material is enormously greater than its capacity for shipping it to Europe, and that we must at once not only balance this production, but slow it down in order to prevent such a choking of our eastern ports as may produce an impossible condition. The five-day shutdown ordered by the fuel administrator and the one-day-per-week shutdown are our first attempts to slow up this production, and we ask ourselves at once if this is the best way. The answer comes that if we are making too much war material we had better turn some of our activities into the manufacture of articles of peace. Immediately we run into the financial situation, which at present seems to seriously hamper new undertakings.

It would seem that the claim of the railroads that they need $1,000,000,000 worth of improvements should at this juncture be considered. Here is one organization now devoted exclusively to the service of the community which, being under the control of the Federal Government, can be financed directly by that government, and there would seem no reason why the production programs of war material should not be limited, and a certain amount of the energy now being expended in that direction turned at once toward the improvement of our transportation facilities.

This is the first suggestion that occurs to one as a means of avoiding the economic situation which seems to be forcing itself upon us. If we can afford to spend billions for war, should not our Government be authorized at once to turn whatever surplus energy has been inadvisedly called into this work into channels that will be beneficial to the community in time of peace?

Overproduction a Menace

After nine months of confusion, it is becoming perfectly clear that as far as we are concerned, in this country at least, our war problem is one of production and transportation on a huge scale.

The critical point to-day is recognized on all sides to be our ability to transport material to Europe. We have in the past repeatedly had estimates as to what transportation facilities we should have, but it is only recently that any real attempt has been made to study the transportation problem thoroughly and to find out what the limiting factors were and how they could be improved. It is hoped that through the investigation which is now being made we shall shortly have exact knowledge on this subject.

In the meantime, however, we already have approximate knowledge which indicates that our production of war material is rapidly outrunning the possibilities of transportation.

Early in December Dean Schneider, working for the Ordnance Department of the army in Washington, warned General Wheeler, Acting Chief of Ordnance, of the situation which is now impending, and the Ordnance Department began promptly to investigate the subject. Investigations of this subject by one department, however, are not sufficient. Our whole production program must be harmonized with the possibilities of over-seas transportation. In other words, an attempt should be made at once to balance our production of war material of all classes with the possibilities

of transportation, and wherever necessary the production program should be slowed down at once in order that the congestion on our Atlantic seaboard may be relieved. The slowing down of this program means that energies which have been unwisely directed to war activities must be at once transferred back again to the industrial work which has to do with peace and the upkeep of our industrial organization.

This is necessary for two reasons:

First: If we are going to spend fifteen billions per year in war we must produce at least fifteen billions more material than we need for peace times, which means that our working plant must be kept in the best possible condition.

Second: If we do not realize that by the production of a surplus of war material we shall ultimately be compelled to cease that kind of manufacture and thereby suddenly throw out of work large numbers of men, we may precipitate an economic crisis of great magnitude.

Engineers in Training

To the Editor of Metallurgical & Chemical Engineering

SIR:—In the December 15, 1917, issue of your publication appeared an article by Robert Tudor Hill on "Engineers in Training." Professor Hill's orderly presentation of the subject and his carefully compiled tabular illustrations naturally attract the attention of one who is interested in educational work. This is especially true if one has had opportunity to observe and ponder over several of the conditions and tendencies to which Professor Hill calls attention.

Readjustment of Engineering Courses

It appears that in many technical schools the broader engineering courses are undergoing a process of remodeling and readjustment from year to year. Several factors are responsible for this variation. Every up-to-date engineering course must keep pace with developments in practice. Both equipment and methods of doing things are improving and changing at frequent intervals. The engineering course which is not adjusted to meet these conditions is not only subject to unfavorable comment from any interested critic, but rapidly becomes uninteresting to the wide-awake student who is beginning to take a serious interest in the field activities of his chosen profession. Therefore, improvement in engineering practice will compel a continual revision of engineering courses.

Another factor which disturbs the stability of an engineering course in some institutions is a process of experimentation which may be described as a struggle to reconcile two opposing tendencies, viz., on one hand to inject into a course the maximum amount of discussion of fundamental theory involved in the subject under presentation, and on the other hand to include in the instruction as many as possible of the so-called professional tricks or kinks used in practice. The first mentioned extreme may make the subject so dry and uninteresting to the average student that he will deny it the attention it deserves, and he may fail to absorb certain important ideas which would be devoured with pleasure if administered in more palatable form. On the other hand, an effort to present innumerable practical frills with the consequent crowding out of valuable fundamental theory results in defeating the very object of ideal instruction, which is to inculcate ability to think properly in the face of an indefinite variety of emergencies, rather than learn how to perform a limited number of set tasks. The young engineer who has a firm grasp on fundamental theory is equipped for professional growth and expansion, and is likely to develop into a citizen of ever-increasing usefulness. The technical graduate who is short on theory may develop cleverness in solving certain problems, but he is likely to lack versatility, his growth may be limited, and he may fail to become more than a first-class mechanic in certain technical activities. The difference between these two products may be chargeable, in part at least, to faulty or inefficient technical training or instruction.

Importance of Study of Economics

If the object of technical education is to develop professional ability calculated to increase industrial efficiency, then no presentation of an engineering problem is complete unless it has been discussed critically from an economic viewpoint. Every engineering project which requires the expenditure of money and contemplates the return of this money together with a profit commensurate with the risks involved, is essentially an economic problem and the technical features are really secondary in importance. If the project will not satisfy a critical investigation from a commonsense, business standpoint, the most interesting technical possibilities of the undertaking are of little consequence. In view of the variety and complexity of the economic factors which frequently demand consideration in passing judgment upon important industrial undertakings, it appears that there is little danger of including too much study of economics in engineering training. It has been pretty well demonstrated that in order to become a safe engineer the technically trained man must first be a good business man.

Consolidation and Expansion of Courses

In the development of engineering courses there are two dangerous extremes which most technical schools endeavor to avoid. Tendency toward these two dangers is a natural consequence of the institution's struggle to crowd the maximum quantity of information into a student in the minimum length of time. This is usually a more serious problem for state institutions, on account of the misdirected and ill-advised political pressure which is sometimes brought to bear upon the governing authorities of the institution. A common example is the school that is compelled to receive the poorly prepared product of the average high school and transform him into the making-of-an-engineer within a period of four years' technical training.

The struggle to meet this condition, and at the same time keep pace with developments in practice, frequently results in the undue expansion of certain courses of study until a definite quantity of useful knowledge is spread out in a thin layer over a considerable period of time. Frequently in this development the apparent improvement in one course is accomplished at the expense of another. A standard and well-balanced course may be forced to concentrate until the time allotted thereto becomes inadequate for the thorough presentation of fundamental principles. This

process may result on one hand in dilation which is nothing but dilution, and on the other hand in concentration which degenerates into a smattering.

Danger of Extreme Specialization

Another struggle between two tendencies is frequently apparent in technical schools, viz., either to produce a jack-of-all-trades who has studied *at* so many different subjects that he has no useful working knowledge of any, or to develop in some one line of investigation such a highly specialized product that his general usefulness in the world is confined within very narrow limits.

It is frequently said that we live in an age of specialization. This is true, but the remark contemplates specialization within sane limits. In this connection it may be fair to observe that the average high school graduate who elects to attend a technical school is usually more mature mentally than the one who decides to follow a liberal arts course. One has decided upon his profession, or has at least determined the general line of activity for which he is best fitted, while the other is still wavering, and may not yet have developed any definite ideas or ambitions as to his probable future career.

This observation by no means assumes that the man who has tentatively chosen his profession is the more intellectual of the two, nor does it assume that he is correct in his estimate of his fitness for the work he has chosen. He may be utterly lacking in certain characteristics which go to make up a successful engineer. A man does not always find his best opportunities in the special vocation which he has chosen. Frequently a technical graduate who has devoted much effort to a certain line of endeavor, and has gained valuable experience therein, finds himself face to face with an attractive opportunity for growth and expansion in some radically different occupation, to say nothing of possible commercial advantages of such a change of labor. This case suggests the advantage of developing in the technical student, so far as possible, a degree of versatility which will relieve him of the necessity of depending upon a single accomplishment for his professional usefulness or advancement.

A frequent danger of specialization, especially in engineering professions, is for the student, and later the engineer, to become what is commonly called narrow. During the intensive study of technical and scientific subjects the student may have absolutely neglected his non-technical education, to his ultimate serious disadvantage in most cases. Usually little or no time is provided for the further study of English or other modern languages, no effort is made to develop ability in technical writing or in business correspondence. The idea that a technical man has a right to acquire a taste for good literature, or that his general cultural development is likely to have a vital influence on his professional career, is frequently ignored in designing a curriculum. Certainly it is a fact that the advantages of developing in an engineer those qualities which are associated with ideas of culture and refinement are seldom even thought of, at least by the student who must later on suffer because of this neglect. Most interested observers can recall more than one case of an engineer who is thoroughly competent in certain technical and business activities, but who is severely handicapped and misjudged because he appears to be positively illiterate.

Preparatory Schools Deficient

A young engineer's ability to seize and make the most of his opportunities may be due to the training he received in high school, where certain tendencies, or habits of thought, or fundamental qualities or ideals were developed and cultivated. Right here in the high school is one of the most important periods of a young man's education. For the student who intends to go to college or university it is of vital consequence. While the high school is in many respects the most important link in our educational system, it is at the same time the weakest. The average high school throws away its opportunity. Lucky is the technical man who has learned in his high school course how to speak and write his native language correctly and has mastered elementary mathematics, physics and chemistry. Many an engineer owes his cultural accomplishments and his taste for good literature, which are a never ending source of satisfaction and advantage, entirely to his high school instruction. Unfortunate is the technical school man who has been denied the refining and broadening influence of an efficient high school course. Few technical schools have time, or take time, to supply the kind of instruction and training that marks their graduates as men of liberal education.

Observation of modern tendencies in high school instruction is not reassuring to the seriously interested critic. During the past fifteen years or more almost all high school courses, which were formerly calculated to prepare the student for university training, have sadly degenerated. High school teachers of long experience, who are disposed to be frank in the matter, admit this to be true. There is a growing disposition to let down the former standards to the extent that the university finds it necessary to devote undue time and attention to the review of many subjects which should have been mastered in a preparatory school. This degeneration appears more serious when we realize that a large proportion of young Americans never complete or pass beyond their high school course, and that with deficient instruction the high school is losing its last opportunity to impart valuable knowledge to future citizens. High schools seem to have developed a policy of graduating the greatest possible number without regard to quality of work. To some extent this policy is forced upon the high school by the tax-paying public which demands that the school increase its sphere of usefulness by imparting a little more knowledge to a great number of future citizens. The so-called vocational training movement has done much to lower the general quality and standards of high school instruction, and to diminish its usefulness as a preparatory school for those who contemplate higher education. This observation is not intended to imply that vocational training in the high school, and its effort to turn out more graduates of poorer average quality is wrong from every viewpoint. If we adopt as our guiding principle "the greatest good to the greatest number," then the modern tendencies in high school instruction may be admirable in theory. Advocates of this principle point out that relatively few high school graduates go to the university, and hence it is unfair to regulate high school standards for the benefit of the

minority. There is little consolation in this argument for those who do contemplate higher education, and the suggestion is made that these students should receive separate or supplementary instruction calculated to supply their needs. While it may be admirable to increase the number of slightly better educated citizens by designing high school instruction to fit their requirements and capacities, it is also important to look to the welfare of that less numerous class that continues its development, and from which many of our leaders of thought are destined to be chosen.

Conclusions

The above informal and somewhat rambling observations lead naturally to the conclusions reached by Professor Hill. All of his eight conclusions are interesting and worthy of careful consideration, not only by designers of technical curricula but also by those who have power to influence the efficiency of the preparatory school training. Preparatory schools should give most serious attention to his conclusion No. 5, which states: "Readjustments in preparatory and earlier secondary school training are desirable so that preliminary training may be completed earlier. This will save time below and gain time above." In other less elegant words, our educational system would be greatly improved if the average high school would do its duty and quit "passing the buck" to the university. Again, the technical school should take to heart his conclusion No. 8, which is in part: "Non-technical instruction for technical students must be as efficient as technical instruction." It is to be hoped that technical schools will interpret these words to mean that it is worth their while, from selfish as well as altruistic motives, to make every reasonable effort to produce "well-informed business gentlemen" rather than "crude skilled technicians."

Origin of the Nebraska Potash Lakes

To the Editor of Metallurgical & Chemical Engineering

Sir:—The very evident interest which the chemists of the United States are bestowing upon potash products and the importance of the Nebraska Lakes has emboldened me to write you a somewhat geological letter dissenting from the usual views held as to the source of the solutions in the saline lakes which are now providing the bulk of this country's available potash. This question is of great importance, since the accepted views set forth in your recent article on "The Nebraska Potash Industry" (Metallurgical and Chemical Engineering, Vol. 17, p. 673, Dec. 15, 1917) that the lakes are merely concentrations of wind-borne plant ashes, give a distinct limit to the amount of potash available from this source. An intensive study of the sand-hills region and its vicinity has brought so many facts to light which are at variance with this hypothesis that I have concluded that the source of the potash is from ground waters circulating through the underlying sands. If this be true, the amount of available material is enormously greater than possible under the former hypothesis. I base my theory on the following observed facts:

Following the upheaval of the Rocky Mountains were numerous periods of erosion and deposition. The material being eroded from the slopes was carried eastward from the divide and deposited in an inland sea covering what is now the High Plains area. The product of this entire period formed rocks and strata in that region which we now term the Tertiary series. There are some fifteen members of the Tertiary, all being conglomerates, varying chiefly in the predominance of lime or silica present. Thus some of them, such as those called the Niobrara by the geologist, are limestones, while the Arikaree and Ogalalla are calcareous sandstones.

As the inland sea receded, erosion of the lake bottom commenced, and the present sand-hill area was formed from these calcareous sandstones by the simple process of the removal of the cementing material by surface waters.

A chemical analysis of the cementing material of the present consolidated strata shows it to consist of a mixture of calcium, iron and aluminium salts, together with high percentages of potash and soda (25 to 30 per cent). These bases are combined in a complex manner as chlorides, phosphates, carbonates and sulphates, and were evidently derived from the original feldspathic granites of the Rocky Mountain uplift.

Since the potash lakes are found chiefly in the area covered by the Arikaree formation, and since this formation has been found to contain the highest percentage of potash of any of the Teritary, it is reasonable to attribute tentatively the lake deposits to the potash-bearing Arikaree. This is especially reasonable when it is known that the bulk, or sand (aggregate) of the Arikaree consists of orthoclase feldspars containing from 20 to 35 per cent of potassium in the form of potassium aluminum silicate and the cementing material is a mixture of lime, iron, soda and potash salts containing from 10 to 30 per cent of the latter.

Generally speaking, the lakes of the potash area contain about 40 to 60 per cent total alkali, the better lakes running high in potash (25 to 30 per cent), while the poorer, or alkali lakes, contain from 8 to 15 per cent of potash and 25 to 40 per cent of soda. I believe this variation is best explained by the supposition that the latter lakes represent those which are geologically older, or which are in proximity to some well-defined underground drainage course. It is well known that old topography is characterized by well defined drainage courses.

Since the potash salts are generally the most soluble, they will pass into the ground water more readily than the other salts. Hence we have soda lakes in the eastern portion of the sand-hill area where the drainage is quite mature, and potash lakes in the western part where the concentration is in progress.

The lakes are largely supplied by subsurface drainage from the Arikaree formation still *in situ* to the north and west, and from which there is no apparent outlet for these solutions, owing to the lack of any well defined system of creeks and rivers. There are numerous lakes in the catchment area of both the Platte and the Niobrara rivers, but these are fresh water lakes, since the alkali salts are continuously removed by the natural drainage. Surface potash lakes, on the other hand, exist on the consolidated Arikaree tableland adjacent to Alliance, at a considerable distance from either of these rivers. These later lakes represent the period very early in the life-cycle of a potash lake.

North Platte, Neb.

Electrolytic Pickling of Steel

To the Editor of Metallurgical & Chemical Engineering

SIR:—In your issue of Dec. 15, Prof. M. De Kay Thompson and F. W. Dodson describe some tests which they made comparing electrolytic pickling with chemical pickling. They used black sheet-iron and found that the surface after electrolytic pickling was "much better" and was "a silvery white and very clean" while that treated by the usual chemical process "was not so clean, but was covered with fine black particles which did not wash off easily but which could be removed by rubbing." On this basis they compared the amount of acid and iron in the final solution and then drew their conclusion.

This is on its very face an unfair comparison and misleads those who may be interested in the process, for it is evident that the chemical pickling had not been carried far enough to remove all the scale, and if it had been there would necessarily have been a much greater amount of acid and metallic iron consumed than they found. To "rub" and rewash the iron in large works would increase the cost greatly, but in their academic tests they entirely neglected this important additional cost.

One of the chief advantages of the electrolytic process is that all these deep-seated "black particles" can be dissolved off without dissolving any appreciable metallic iron and without uselessly consuming the corresponding acid. While with the chemical process the most wasteful consumption of metallic iron and the corresponding acid takes place just when these deep-seated "black particles" are being removed, if indeed the process is carried so far, as that leaves the surface deeply pitted. Had they carried the chemical pickling far enough to remove all the oxide to the extent to which it was removed electrolytically or even only approximately, their consumption of metallic iron and acid would have been far greater.

Moreover, in the chemical process they filtered off the scale so that no acid would be consumed in dissolving it. This is academic, as it is not done in practice and would be quite expensive. While the scale is not directly soluble chemically in sulphuric acid, yet when reduced by hydrogen it becomes soluble; and as the agitated liquor is always full of hydrogen considerable of the removed scale in the bottom of the vat no doubt is ultimately dissolved, thereby consuming additional acid quite uselessly, as the object of the pickling had then been accomplished.

Furthermore their acid for chemical pickling was stronger that what I was informed was used in practice, while for the electrolytic process it was weaker than what it should have been; both give undue favor to the chemical process and are therefore unfair and misleading.

That they did not carry out the electrolytic process properly and therefore got wrong and misleading results, is shown by the very low current densities they used, and it was for this reason that the iron was not sufficiently protected by the current and may have been partly dissolved, thereby also uselessly consuming acid. One of the important features about the electrolytic process is that the high current density prescribed protects the clean iron from being dissolved. I have treated a cleaned piece of iron electrolytically at the proper current density about fifteen times as long as it takes to clean it and yet found that it had lost practically nothing in weight, while treated proportionately long by the chemical process the sheets would probably have had actual holes eaten through them. Had they carried out the process as prescribed in the patents they should not have lost an appreciable amount of metallic iron. Moreover, the higher current density would no doubt have also reduced the time required; but even so, when the scale was thick they found it took only 8 minutes as against two and a half hours for the chemical pickling.

In a letter to the writer Professor Thompson states: "I think there probably is very little metallic iron dissolved in the electrolytic method, but we did not determine this." Unfortunately his article gives quite the contrary impression. He adds: "Perhaps it should have been stated (in the article) that no attempt was made to distinguish between the two sources of dissolved iron," meaning whether it had been useful metallic iron or useless scale.

They used the lower current density because they claimed to have found the current "efficiency" to have been greater then. This is academic; the current in the electrolytic process is but a small item of the cost, while the metallic iron lost, with the corresponding acid, is a large item.

The commercial man rightly looks after the dollar; to save a little in a cheap item and thereby lose a lot in an expensive item is not good practice, even though it may appear to be better academically.

It is manifestly not fair to the electrolytic process to conclude from the iron found in solution afterwards that this was originally metallic iron, which is certainly the impression they give when they say that "the amount of iron dissolved was 2.88 grams," or such-and-such per cent of the original oxidized sheet. When properly carried out the iron in solution comes from the scale alone, while in the chemical process it necessarily was nearly all good metallic iron, as they say they filtered off the scale which drops off by dissolving the iron underneath.

Academic tests can be very misleading and deceiving when proper consideration is not given to the factors which are of chief importance in the industrial applications.

Some of the writer's tests were described in METALLURGICAL AND CHEMICAL ENGINEERING for November 1, 1915, p. 785.

CARL HERING.

Philadelphia, Pa.

Permits for Potash Exploration.—Under a recent law permits may be issued for the exploration for potash on tracts of land not to exceed 2560 acres. These permits run for two years, and if potash of commercial quality and quantity is discovered, the permittee will be given a patent for one-fourth of the land covered by his permit, and the remainder may be leased by the Government to others. Secretary of the Interior Lane recently issued the first prospecting permit under this law, covering 2560 acres of alkaline marsh land in the desert region of Inyo County, California, and the permittee expects to promptly begin explorations by sinking wells. Other similar permits will be issued in the near future.

Western Metallurgical and Chemical Field

Canadian Lead Situation

WITH the resumption of operations at the lead smelter of the Consolidated Mining and Smelting Company at Trail, British Columbia, the Canadian lead situation enters upon a new phase. During the early part of 1917 the 12-cent lead market, and the prospect of dollar silver induced miners in British Columbia to extend their production to the utmost. This ore, sent to the smelter at Trail, soon built up a formidable surplus, receipts during the first week in October amounting to the record quantity of 12,600 tons. By this time the lead market had dropped to 7 cents with a prospect of a further decline, the Canadian market was very quiet, and in order to protect itself the smelting company issued a notice stating that lead ores containing more than 4 per cent zinc would no longer be accepted. Since such action would cut off shipments from practically every independent producer in British Columbia—that is to say, in Canada—immediate pressure was brought to bear upon the government to remove the export embargo then existing on lead ores, which the Dominion government decided to do. The greater freight rates to the Tacoma and other smelters in the United States, together with a 6-cent lead market, did not promise much relief to the Canadian miners, however, but meanwhile the Trail smelter announced that after November first it would accept shipments on the basis of the average shipments of the past twelve months. This action on the part of the smelting company was possible following the receipt of a substantial order from the Imperial Munitions Board, which with other orders on their books would assure normal smelting operations until the spring of 1918.

Shipments had hardly been resumed, however, when a very ill-advised and hasty strike shut down the Trail plant for several weeks, again deranging the economic life of the province. On investigation the International Mine, Mill and Smeltermen's Union declared the plant "fair" and censured the local for violating their agreements, whereupon the smeltermen resumed work under their old sliding-scale contracts at lower wages than before the shut down, the price of lead having dropped meanwhile.

Despite these vicissitudes, the production at Trail was 22,130 tons of lead during 1917, which figure is about 2000 tons in excess of that of 1916. Since Canada is making an effort to be self-contained, at least as far as lead is concerned, the possible disposition of this amount of metal within the Dominion is causing considerable discussion. During the preceding years considerable quantities went into munitions, mostly as shrapnel bullets. However, the large Canadian munitions orders early in the war were financed by the Imperial Treasury, as pointed out by Alfred Stansfield in the December bulletin of the Canadian Mining Institute. Since those days Great Britain has been able to increase largely the production of her own factories, and the lack of funds has made it necessary for her to order supplementary material from countries which can loan her enough money to pay for them. Hence the further production of Canadian munitions consuming lead must be financed by Canada herself, and it would require shrapnel worth twenty million dollars to absorb the 10,000 tons of lead annually produced in Canada in excess of her normal peace requirements. Even this material after manufacture may be impossible to ship through the submarine zone, and Prof. Stansfield feels that a more rational outlet for the excess lead is as lead compounds or to replace those lead articles now imported. Before the war Canada consumed annually 30,000 tons as metal and in compounds, while its annual production amounted to but 19,000 tons. While imports of white lead are constantly decreasing, in view of the growth of the Canadian corroding industry, much litharge is still imported and could easily be made locally. The manufacture of sheet lead, lead pipe, and other like products is also a possibility, but only if the Canadian market is assured.

Nebraska Potash Production

As a general proposition it is safe to say that the Nebraska fields have not produced the expected amount of potash during 1917. One plant fell short of its estimates at least 1500 tons due to a variety of causes—labor difficulty, fuel shortage, and the extreme cold weather which cut down the efficiency of the evaporating plants enormously.

The outlook is good for a larger production during 1918, however. Three new plants are in course of construction at Antioch. One owned by the Alliance Potash Company expects to begin operation in May. The other two will doubtless make strenuous efforts to start before the next winter sets in, and they may contribute materially to the total for the year. Building is necessarily slow, owing to the great difficulty in obtaining materials and evaporating equipment. In fact, it is almost impossible for operating concerns to procure certain classes of supplies, such as valves, for instance, and these things are ordinarily rebuilt in their machine shops in order to keep the plants running. Since most of the nearby lakes have been drawn from, the newer plants will face a question of piping the brine long distances.

Shortly after the Government took over the control of the railways extreme difficulty was experienced in getting a supply of oil and coal, but these matters are better adjusted at present, and regular shipments of coal are being received. The oil situation is still causing the operators much uneasiness, the Standard Oil Co. not being able to give assurance about deliveries as to time or quantity. Consequently, fuel oil necessary for the operation of the rotary driers has been shipped from as far as Texas, making the cost almost prohibitory. The labor situation has been better this winter than at any other time since the development of the lakes, cold weather may have an important effect on keeping the floating labor stationary, however.

New Smelter in Arizona

The United Verde Extension Mining Company is constructing a new smelter on a site near the Verde River, about three miles south of Clarkdale, Ariz., where the older plant of the United Verde is situated. The copper ore will be milled to the lowest levels of the mine, which is situated at Jerome, and hauled by standard gage equipment through a haulage tunnel and thence over a private railroad to the smelter bins.

The plant will consist of six roasting furnaces, two reverberatory smelting furnaces, one blast furnace and

three converters. It has been designed with especial attention to future extensions; any part can therefore be enlarged without interfering with the operation of the previously completed portions.

The roasting plant is similar in detail to those now in operation in the most up-to-date smelters in the southwest, the general features of which have already been described by the designer at the Arizona meeting of the American Institute of Mining Engineers.* The furnaces are of the Wedge type, each having its own motor drive.

The reverberatories will be 25 ft. wide and 120 ft. long, and will be fired with pulverized coal. From an improved type of car, the calcines will be dumped into large bins above the firing end of the furnace, from which they will be drawn by scraper conveyors along each side of the furnace, and charged by means of pipes through the furnace roof at intervals of approximately 30 in. along the skewback.

The blast furnace will be 48 in. by 320 in. in size. Coke and ore bins will be placed on either side of the furnace above the charge floor. These bins will be filled by conveyors from supply beds, and will be drawn off into electrically operated charge cars.

The converters will be of the Great Falls type, 12 ft. in diameter, and served by a 40-ton crane. Silica will be charged through conveniently located spouts leading from bins placed above and to the rear of the converters. These bins will be filled with crushed flux by means of suitable belt conveyors.

It had been the intention to start the smelter on April 1, but numerous delays in delivery of material will probably set the date a few weeks later. A. G. McGregor, of Warren, Ariz., is the designer of the plant, and Barry Hogarty is Superintendent for the United Verde Extension Mining Company at the smelter site.

By-Products from Colorado Smelters

In the report of the Colorado Smelter and Ore Sales Investigating Committee, the following statement is made relative to the recovery of by-products at Colorado smelters:

There are two smelting plants in Colorado equipped with baghouses for the recovery of the voltailized material from the blast furnaces. That portion which is volatilized in the roasting of the ore is not recovered at any Colorado plant.

In addition to the recovery of gold, silver and lead from the flue dust and baghouse product, arsenic and cadmium are recovered at the Denver plant. The arsenic plant at Denver treats the flue dust and baghouse product from all company plants. The maximum output of the plant is 120 tons per month of arsenic trioxide.

The cadmium plant at Denver treats the baghouse product supplied from various smelting units of the company, many of which are operating outside the state. The maximum output of this plant is four tons per month.

A small quantity of bismuth was produced from the Leadville plant.

The production of these by-products is the result of the concentration and accumulation of the material treated. With the exception of possible special occurrences, these metals are probably associated with others, and the quantity in the original is so small that the extra expense of its recovery from the crude ores would not be justified, and no accounting is made of their value in the purchase of the ores for the smelters.

Arsenic and bismuth are usually found in combination with sulphur, and cadmium accompanies zinc, and they are all susceptible to high loss from volatilization.

Rapid Growth of American Magnesium Industry

WHEN the European war started, practically all of the magnesium used in this country came from Germany. It soon, however, practically disappeared from the market here and the price soared up to a prohibitive figure so that many manufacturing concerns discontinued its use. It is now being made in this country in comparatively large quantities and the price has now been reduced and is approaching that which was general before the war. It is being sold in small lots for not over $2.00 per pound and in large quantities very considerably below this figure.

According to a preliminary report just issued by Frank L. Hess of the Geological Survey, four American firms were responsible for all the production of magnesium in the United States in 1916—75,400 lb., valued at $311,570. In 1917 five firms produced 115,800 lb., valued at $233,600. In spite of an increase of 65 per cent in quantity there was a decrease of 25 per cent in value, for the average price fell from $4.13 a pound in 1916 to $2.10 a pound in 1917. The price early in 1916 reached $5 a pound. Late in 1917 it fell to $1.85 a pound.

In 1916 magnesium was made by the Electric Reduction Co., Washington, Pa.; Norton Laboratories (Inc.), Lockport, N. Y.; Rumford Metal Co., Rumford, Maine, and General Electric Co., Schenectady, N. Y. The Electric Reduction Co. has found it more profitable to use its power for other purposes, but the other companies named produced magnesium in 1917. The American Magnesium Corporation, the successor of the Aviation Materials Co. at Niagara Falls, made an output in 1917, and the Dow Chemical Co. began production at Midland, Mich., but was prevented from operating at its full capacity by shortage of coal. The General Electric Co., which in 1915 had been forced to make magnesium in order that it might have the metal it needed for its own work, closed its plant in 1917, as the industry is now well established in this country and the price has fallen to a point near that which prevailed before the war.

The Rumford Metal Co. and the American Magnesium Corporation have investigated and produced alloys of magnesium with aluminium, calcium, copper, iron, nickel and silicon. The latter concern is producing an alloy containing 50 per cent magnesium and 50 per cent copper and an alloy containing 20 per cent magnesium and 80 per cent copper. The company has furnished us with the following information concerning these alloys:

"For use as a deoxidizer and scavenger in copper, brass, bronze and phosphor-bronze castings.

Magnesium in small quantities, in copper, brass and bronze castings, has a beneficial effect, making the metal close grained and having superior physical properties. In phosphor-bronze, an excess of magnesium produces pin-

holes and other imperfections in the castings but a small quantity results in much improved metal.

Use a small quantity of magnesium, of about 0.05 per cent, which is amply sufficient for deoxidizing purposes. Probably one-half of this quantity will give even better results in alloys containing zinc, such as brass or bronze, for the reason that there is less oxide to be reduced than in metals like copper or nickel.

Magnesium is, theoretically, a better deoxidizing material than a non-metal like phosphorus. This alloy should be used in copper castings, where high electrical conductivity is desired. It is prepared simply to facilitate its use in the foundry, as magnesium alone is very light and floats and burns on the surface of molten copper and brass unless special precautions are taken to keep it submerged.

One of the principal uses of magnesium is for alloying with aluminium for airplane parts, where lightness is important. By the proper combination of magnesium, aluminium and other metals, in small quantities, an alloy can be produced which will reduce the weight nearly one-half below the weight of No. 12 aluminium. Magnesium is being used more and more as a deoxidizer and scavenger for copper, brass and bronzes and a new alloy of magnesium has been prepared for use as a deoxidizer and scavenger for high grade tool and alloy steels. Another large use of magnesium is in the powdered form for light bombs and flares for lighting night attacks on the European battlefields.

The following references to the use of magnesium have been kindly furnished us by Mr. I. R. Edmands, president of the American Magnesium Corporation:

Brass and Bronze.—An excess of magnesium can be used in deoxidizing without working harm.[1] Usually 0.05 per cent in the case of brass is sufficient. 0.05 per cent increased tensile strength of brass 30 to 50 per cent. 0.05 per cent increased tensile strength of bronze 25 per cent. Elongation increased 40 per cent in both cases.

Copper.—Copper refined in the following way was found equal to the best electrolytic copper.[2] The copper charge is melted in a graphite crucible and the oxides reduced by the addition of 0.1 per cent magnesium in the form of a copper-magnesium alloy containing 20 per cent magnesium. A bi-silicate slag is useful as a solvent for the MgO. Magnesium may be employed for removing the last traces of oxygen from copper that has already been partly refined in the usual way.[3] An excess of magnesium over that necessary to combine with the oxygen must not be used. The copper should be covered by acid slag, or a boric acid flux, with which the MgO will combine. Magnesium is the most satisfactory agent for the deoxidation of copper according to Sperry.[4] The magnesium in the form of bars is alloyed with 90 per cent copper before introducing it into the melt so that it will not float on top. The Mg-Cu ingot is stirred into the metal with a plumbago stirrer. A great advantage of the magnesium is that it decomposes the gases occluded in the melt as well as combining with the oxygen. Thus, CO, which is present in larger proportions than any other gas, is reduced to carbon.

Magnesium-Aluminium Alloys.—An alloy of the following composition has been patented by Chemische Fabrik Griesheim-Elektron:[5] Magnesium 92 per cent; aluminium 8 per cent. Specific gravity 1.75. Strength equal to that of gun metal. The presence of a small quantity of magnesium in aluminium hardens the latter very considerably according to Wilson.[6] Microscopical examination reveals no change in the structure of the metal. The hardening of the metal is accomplished by heating to 500 deg. C., quenching in water and allowing to stand. This hardness develops gradually, as well as an increase in strength and ductility. The metal should not be worked directly after hardening. Heating to 200 deg. C. after this treatment causes a distinct loss of hardness. In the manufacture of magnesium-aluminium alloys according to Klaudy[7] it is of importance that the metals be pure. 10 to 30 per cent magnesium gives an alloy of great strength and easy to work. 2 to 10 per cent produces one that is easy to draw and to roll. Heavy metals can be added to the alloy in such quantity that the resulting density is not greater than that of aluminium. He gives 2 to 5 per cent magnesium as best for wire drawing; 5 to 8 per cent magnesium as best for rolling, and 12 to 15 per cent magnesium as best for casting (pouring). In making alloys of magnesium and aluminium,[8] the aluminium is melted in a graphite crucible and a small amount of cryolite added as a flux. The magnesium is introduced and held beneath the surface with tongs. The average strength of cast 10 per cent magnesium alloy is 20,000 lb. per square inch. Such an alloy possesses an unequaled lightness, the hardness of brass and the strength of cast iron. An alloy recommended for automobile and airplane construction has the following constitution:[9] Aluminium 70 to 90 parts, magnesium 5 to 18 parts, cadmium 2 to 12 parts.

It is most likely that the extent to which magnesium is used will depend on its selling price, and many new uses will undoubtedly be found as the price decreases. We have only to refer to the interesting history of aluminium to obtain an idea as to what is possible with magnesium if it can be produced at a low enough price.

Status of "Non-Essential" Industries

The Fuel Administration has worked out a plan which provides, in part at least, for necessary restrictions with the least possible injury to industries. This plan provides for fuel curtailment by voluntary agreement among representatives of non-war industries. The effect will be to limit production and make a corresponding saving in transportation and in materials needed for the war. The plan has been tried extensively enough to prove its practicability.

Nevertheless there may be need for more than voluntary co-operation, and for that reason the War Industries Board should immediately list those industries which, as war measures, are of *exceptional importance*. It should determine also, after due notice and hearing, which are the less important industries, measured by the extent of their contribution toward winning the war, and should then announce its findings and enforce plans which will (1) stimulate the operation of industries of exceptional importance, and (2) curtail the operations of the less important, or preferably encourage them to so change their operations as to produce war needs. These are unofficial views of a representative of the War Industries Board.

Platinum Industry Under Government Control

THE production, refining, distribution and use of crude and refined platinum was placed under government control March 1, 1918, for the period of the war. The Council of National Defense has issued a statement on the subject which says that the control will be exercised through the chemical division of the War Industries Board. The chemical division has sent out to the industry requests for inventories of the existing stock of crude and refined platinum and platinum-iridium alloys as of March 1, 1918.

The letter stated that it was not the intention of the government to take over and handle directly the present stock of platinum but to permit its shipment by the producers or dealers subject to certain conditions.

Upon the fixing by the Secretary of War of a reasonable price for crude, refined and alloyed platinum, notice will be given and blanks issued governing delivery and distribution.

The letter sent out by the chemical division includes the following directions to producers:

"1. That producers, refiners and dealers in platinum continue to dispose of their product for government purposes, and for that only, as directed by the chemical division.

"2. That producers, refiners and dealers in platinum who are also consumers use platinum for government purposes, and for that only, as directed by the chemical division.

"3. That all obligations arising out of transactions in the production or delivery of crude, alloyed or refined platinum released as above, including all claims for shortage, poor quality, damage or loss in transit, be borne by the producer or seller, as the case may be, in accordance with existing trade practices.

"Distribution may be made by consent of this board through agencies under existing arrangements, provided that there results no increase over the existing price to the user.

"The undersigned, on separate application in each case, will consider permitting the delivery of a limited amount of platinum for essential commercial purposes not for government account.

"Proper blanks upon which application for release of shipment should be made will be furnished on application.

"The following list indicates, in general, the order of preference which will be followed in releasing platinum for shipment: First, military needs of the United States Government; second, military needs of allied governments; third, essential commercial purposes."

* * *

A supplementary notice sent from the Council of National Defense states that in issuing Ordnance Requisition No. 510, commandeering crude or raw platinum now in the hands of importers or refiners of this precious metal, it is to be understood that this commandeering order does not apply to or interfere with the purchase by the consumer of any manufactured articles containing platinum.

This explanation is made so that the public may clearly understand the purpose of this action by the government.

Water-Power Hearing at Washington

THE week of March 18 will be devoted by the joint water-power committee of Congress to hearings on the provisions of the so-called Administration Water-Power bill. The main features of this bill have been set forth in previous issues of this journal, but are briefly reviewed here together with some amendments which have been suggested by the Secretaries of War, Agriculture and the Interior.

The bill is proposed as a House substitute for Senate bill 1419, known as the Shields bill, which was passed by the Senate in the last Congress. It provides for a Federal Power Commission, for the improvement of navigation and the development of water power. The Commission is empowered to issue licenses

> "for an original period of fifty years, unless a shorter time is agreed upon between the applicant and the commission or is necessary in order that licenses for parts of the same project shall terminate on the same date. Licenses for subsequent periods of such duration and under such conditions as may be prescribed by then existing law and regulations shall be tendered as provided * * * unless and until at the termination of the original, or of any subsequent period, the properties are taken over and compensation made as provided * * *."

An annual charge of not less than 10 cents per horsepower per annum is to be made and paid into the United States treasury. The funds thus accumulated are to be divided for the construction and maintenance of roads in national forests, for the improvement and development of national parks and monuments, maintenance and operation of dams, etc.

The recapture by the government of any projects developed under the terms of the bill may be effected by paying the net investment of the licensee. Net investment is thus defined:

> "'Net investment' in a project means the actual legitimate original cost thereof as defined and interpreted in the 'Classification of investment in road and equipment of steam roads, issue of nineteen hundred and fourteen, Interstate Commerce Commission,' plus similar costs of additions thereto and betterments thereof, minus the sum of the following items properly allocated thereto, if and to the extent that such items have been accumulated during the period of the license from earnings in excess of a fair return on such investment: (a) Unappropriated surplus, (b) aggregate credit balances of current depreciation accounts, and (c) aggregate appropriations of surplus or income held in amortization, sinking fund, or similar reserves, or expended for extensions or betterments. The term 'cost' shall include, in so far as applicable, the elements thereof prescribed in said classification, but shall not include expenditures from funds obtained through donations of States, municipalities, individuals, or others."

If the project is not recaptured by the United States or by a new licensee,

> "the terms and conditions imposed upon the original licensee in any new license tendered shall not be such as to impair the net investment of the licensee in said project or projects."

Intrastate rates and service are to be regulated by state commissions charged with such powers. Interstate rates and service are within the jurisdiction of the federal power commission.

It is understood that the hearing is to be brief and to the point. The general features of water-power legislation have long since been threshed out, and what is now needed is a final agreement on the broad aspects of the bill. Criticism should be confined to constructive comment on the more important factors and should not extend to petty, relatively unimportant details.

Fertilizer Industry Under License

UNDER a proclamation recently issued by President Wilson the importation, manufacture, storage and distribution of fertilizers and fertilizer ingredients are placed under license and are required to obtain license before March 20 in order to continue business. The following commodities are affected: Fertilizers and fertilizer ingredients, including sulphuric acid, phosphate rock, acid phosphate, bones (raw, ground or steamed), bone black, basic slag, sodium nitrate, ammonia sulphate, cottonseed meal, slaughterhouse tankage, garbage tankage, castor pomace, fish scrap, base goods, cyanamid, calcium nitrate, dried blood, acidulated leather, hair, hoof meal, horn dust, ground leather, other unacidulated ammoniates, potash salts, cement dust, blast-furnace dust, kelp ash, kelp char, dried kelp, wood ashes, cottonseed hull ashes, potassium nitrate, tobacco waste, mixed fertilizers, sulphur, and all other fertilizers and fertilizer ingredients.

The order does not apply to companies to which licenses have already been issued under the proclamation of the President of Jan. 3, 1918, relating to ammonia, ammoniacal liquors and ammonium sulphates. The Secretary of Agriculture is empowered to carry the act into effect. Licenses are issued through the Law Department, License Division, U. S. Food Administration, Washington, D. C.

Delaware Chemists Discuss Manufacture of Nitric Acid

The second meeting of the recently formed Delaware Section of the American Chemical Society was held at Hanna's Café in Wilmington on Friday evening, March 8. An address was given by Dr. Edward Hart of Easton, Pa., on the "Manufacture of Nitric Acid." Dr. Hart is director of the Hart Laboratories of Easton and was formerly head of the chemical department of Lafayette College and president of the Baker & Adamson Chemical Co. He is one of the pioneers in the manufacture of nitric acid and originated the Hart condenser, which is used in a modified form in the majority of nitric acid plants here and in other countries except Germany. An abstract of his address will be given in a later issue. Dr. Charles L. Reese, chemical director of the E. I. du Pont de Nemours Co., was present and took part in the discussion. The meeting was presided over by J. E. Egleson, manager of the General Chemical Co.'s plant at Marcus Hook, the chairman, Mr. Lamont du Pont, being unable to attend.

The Delaware Section is an outgrowth of the Delaware Chemists, a former du Pont society, and the Philadelphia Section. It is already very active and has about 150 members. In the district below Philadelphia, on both sides of the Delaware as far as New Castle, it is estimated that there are 500 chemists in the various chemical, explosive, iron and steel and other plants.

Dr. R. P. Calvert of the Experimental Station of the E. I. du Pont de Nemours & Co. is secretary of the section and F. W. Barker of the National Aniline & Chemical Company's plant at Marcus Hook is chairman of the membership committee. The next meeting of the section will be held on the second Friday in April, at which Dr. Charles L. Reese will give an illustrated talk on explosives.

Presentation of Nichols Medal to Dr. Treat B. Johnson

At the regular meeting of the New York section of the American Chemical Society held at the Chemists Club, March 8, the Nichols Medal was presented to Dr. Treat B. Johnson, professor of organic chemistry in the Sheffield Scientific School of Yale University. The award had been made in recognition of Dr. Johnson's contribution to organic chemistry, particularly in the synthesis of pyrimidines.

Dr. Charles H. Herty, chairman of the New York Section opened the meeting with a statement, in part as follows:

> It is a striking fact that in the midst of feverish war preparations, while our minds are filled with death-dealing chemical reactions, we are met together this evening to pay tribute to a quiet worker in the university laboratory, who with infinite patience and consummate skill has accomplished brilliant results in an extremely complex and difficult field of chemical research, that dealing with the fundamental processes of life. I take it as a healthy sign and one presaging great good to chemistry in America that in these days of intense application of science to industrial processes the worker in pure chemistry has been chosen as the recipient of the Nichols Medal.
>
> Under the terms stipulated by its donor, Dr. William H. Nichols, whom happily we have with us to-night in the capacity of leader of the organized chemists of this country, this medal is awarded annually by our Section to the author of the best original article published during the preceding year in the journals of the American Chemical Society. In reaching its decision the committee has construed broadly the conditions of award, realizing fully that in certain lines of research results cannot be withheld indefinitely in order to present in one contribution a comprehensive report of an entire investigation. Such action might lead to loss of priority, and would undoubtedly diminish that stimulative effect which follows the publication of definite chapters in the progress of investigation which in its very nature must require years for completion.
>
> On the basis of such broader interpretation of the terms of award the committee has this year unanimously awarded the medal to Dr. Treat B. Johnson, Professor of Organic Chemistry in the Sheffield Scientific School of Yale University. During the past year Dr. Johnson contributed four articles to the Journal of the American Chemical Society. A fair measure of his activity can be gained from the fact that these four constitute the continuation of a series of one hundred and fifty-four contributions in which his name has appeared as author.
>
> Through this multitudinous array of original communications Dr. Johnson has shown his courage and ability in bringing light into one of the darkest and yet most important fields of chemistry. In reading the advance copy of his address, and noting the brilliant progress he has made through calling the element sulphur to his aid, I am almost forced to describe his activity as devilish. Beginning in 1898, the output of papers from his laboratory has been continuous—two decades of accomplishment to which we all join in paying heartiest tribute.
>
> We are interested to-night, however, not only in the scientific achievements but in the personality of the man whom it is our privilege to honor. Like so many other great Americans, he was born "down on the farm," near Bethany, Conn., on March 29, 1875. In 1898 he graduated from the Sheffield Scientific School with the degree of Ph.B., and three years later received his doctorate from Yale University, having specialized in organic chemistry. A laboratory assistant during his post-graduate course, Dr. Johnson was in 1902 appointed instructor in chemistry in the Sheffield Scientific School. In 1909 he was promoted to an assistant professorship, and in 1914 was advanced to professor of organic chemistry.
>
> It now becomes my pleasant duty to present to you Dr. William H. Nichols, president of the American Chemical Society, who in his life has taken part in many presentations, and who I am sure will sanction the statement that in no similar occasion has he taken greater pleasure than in this.

In presenting the medal Dr. Nichols facetiously remarked that it had been his pleasure to participate in the presentation of a number of medals, but that he had never been the recipient of any. He declared that "it is easier to give than to receive." After paying a general tribute to the chemists of the United States he expressed a willingness to place his reliance in the American chemist in winning the war and establishing American chemical industry on a sound basis. He said that what he had admired most in Dr. Johnson was not the scientific ability displayed nor the brilliance of the research, but the personal quality which had led him to collaborate with others and permit them to share his honors.

Dr. Johnson expressed his appreciation of the honor conferred and read a paper entitled "The Developments of Pyrimidine Chemistry." This paper is of interest primarily to organic research chemists, as it gives a historical review of pyrimidine chemistry for the past 100 years. It has great importance also for the physiological chemist on account of its bearing on the chemistry of life processes. Dr. Johnson divided his review into historical periods beginning with the discovery of alloxan by Brugnatelli in 1917, and closing with the work of himself and associates in discovering new methods of synthesizing uracil, thymine and cytosine.

War Finance Corporation

A BULLETIN issued recently by the National City Bank of New York contains the following comment on the bill for a War Finance Corporation which has just passed the Senate.

It is generally agreed that the time has come for the government to have control over the investment market, with a view to preventing the absorption of capital and labor in enterprises which are now of secondary public importance, and no doubt there is need for the Government to provide special facilities for financing private enterprises which are engaged in war work or business vital to the general welfare. The plan of the War Finance Corporation is well adapted to these ends. It will be provided with a capital of $500,000,000 subscribed by the Government, and it will be authorized to issue its own obligations, running from one to five years, which may be sold to the public and the proceeds used to carry out the purpose in view.

We have had nothing but commendations for this part of the plan, but have deprecated the proposal to admit investment securities sold for the purpose of raising more or less permanent capital as the basis of loans and currency issues by the reserve banks. We have done so because we are sure there is no necessity for such action, and have misgivings that the grant of power will create strong pressure for its use, and tend to divert attention from the policy of general restraint upon private expenditures, which we believe to be the true one for this time.

So far as protection of savings banks is concerned we have stated that provision to pay their depositors, if there is any occasion for so doing, is not open to the objection raised against supplying money for industry, for if depositors want their money for the purpose of buying Government bonds all payments to them will come into the Treasury and can be returned to the reserve banks as deposits. It is only as loans are made in attempts to enlarge the volume of industry, at a time when by reason of natural limitations, it cannot be enlarged, that inflation occurs. Likewise, refunding operations make no demands upon labor or new capital, and, therefore, do not require resort to the reserve banks.

With a close control over the investment market to restrict the employment of capital to approved undertakings, there is no reason to doubt that there will be plenty of capital to meet the important demands contemplated in the bill. At any rate it is certain that no capital can be created by borrowing of the reserve banks at a time when the working forces of the country are already employed to the limit. The point has been reached then when the relief must come by another method—the method referred to by a member of the Federal Reserve Board in a recent address, as follows:

> The question which I believe, in view of this situation, the country must soon face, is whether it will be the part of financial prudence for us to attempt to finance our Government loans by an expansion of banking credit with accompanying inflation of prices, or whether it will be better, however drastic the steps necessary to accomplish this result may be, to pursue the course of converting the potential savings fund of the nation into an actual savings fund of sufficient magnitude to absorb the loans of the Government as *savings loans*.*

The pending bill seems likely to become a law without important changes, and will doubtless be administered with great discretion. Our attitude toward the questionable feature has been prompted by apprehension that the public would interpret the measure as providing for expansion, and proceed to manage its private affairs in such a manner that the authorities might be compelled finally by resulting conditions to use the new powers to a degree not contemplated at the outset.

The interpretation which at least a portion of the public places upon the measure was stated by the market reporter of the *Wall Street Journal* after it had been reported to the Senate, as follows:

> The economist who argued that eggs now selling at 60 cents a dozen would sell at $1.50 when the War Finance Bill became a law gave an illustration which the public understands. He may not be exactly right on figures, but the financial district sides with him in his argument. It follows that with commodity prices higher many other things which money can buy, stocks included, may sell higher.

This cheerful view is not confined to the stock market, and probably there are more who hold it than there are who understand that to whatever extent the act has influence upon industrial conditions it will increase the cost of the war and the amount which the Government must raise by taxation and loans.

Coming Meetings and Events

Dyestuff Association of America, Rumford Hall, Chemists' Club, New York, March 6.

American Electrochemical Society, Spring meeting, Southern trip, week of April 28.

American Society of Mechanical Engineers, Worcester, Mass., June 4-7.

American Institute of Chemical Engineers, Berlin, N. H., June 19-22.

American Society for Testing Materials, Atlantic City, June 25-28.

*Address of Dr. A. C. Miller before the American Academy of Political Science, Philadelphia, November, 1917.

Dyestuff Manufacturers Perfect Organization

THE American dyestuff industry was formally organized on March 6 at a meeting held at the Chemists' Club in New York. The chief feature of the meeting was the decision of those present to limit the organization exclusively to American manufacturers of dyestuffs and intermediates. A firm stand on this point was taken by a large majority of the principal manufacturers.

The report of the organization committee, appointed at the preliminary meeting on Jan. 22 was presented by Dr. J. Merritt Matthews, the chairman of the committee. He said the various members of the committee had ascertained from as large a number as possible just what kind of an organization would best serve the interests of our dyestuff industry. The committee after carefully considering the matter then adopted a resolution that an organization be formed to be known as the Dyestuffs Manufacturers' Association of America or some similar name, to consist of manufacturers of dyes and intermediates, and that the dealers form a separate organization, if they so desire.

After the recommendations of the organization committee were presented, a lively discussion took place for and against the inclusion of dealers in the association. Mr. H. G. McKerrow, the originator of the organization and a member of the organization committee, presented a minority report of that committee outlining a plan of organization in which there would be three sections, manufacturers, dealers and allied interests. He was very strongly in favor of including all interests.

When it came to a vote on the subject it was seen that practically all of the manufacturers were in favor of an exclusive organization, and a motion was carried that such an organization be formed. There were not more than half a dozen dealers present and about twenty-seven manufacturers. There were also present quite a large number of representatives of allied interests.

The chief points in favor of an exclusive manufacturers' association were, (1) that dealers' interests will not be essentially American after the war, as they will buy wherever they can; (2) that it has been the experience of other associations that the best results are accomplished by separate organizations connected only through their councils, and (3) that most of the manufacturers are averse to having the dealers included.

The chief points in favor of a mixed organization brought out were, (1) that no sharp line of demarcation could be drawn between manufacturer and dealer as many were both; (2) that small manufacturers are dependent on dealers to market their product, and (3) that dealers are apt to work against the best interests of the American industry unless included as a part of the industry.

The following board of governors was elected to formulate by-laws, nominate officers and take up the other problems, such as the tariff, standardization, etc.: G. H. Whaley, John Campbell & Co.; Dr. Poucher, E. I. du Pont de Nemours & Co.; Alfred Blum, United Piece Dye Works; Mr. Jeffratt, Calco Chemical Co.; August Merz, Heller & Merz; Mr. Orth, Marden, Orth & Hastings Corp.; Frank Hemingway, Frank Hemingway, Inc.; L. A. Ault, Ault & Wiborg Co.; J. M. Matthews, Grasselli Chemical Co.; Mr. Cottingham, Sherwin-Williams Co.; Robt. Kemp, Read-Holliday & Co.; R. P. Dicks, Dicks, David & Co.; I. V. Stanislaus, Stanley Aniline & Chemical Co.; E. H. Killhefer, Newport Chemical Works.

What the Tariff Commission Is Doing

The following subjects included in the chemical schedule have been undertaken for study by the Tariff Commission and co-ordinated reports of all available information are under way for the use of Congress. Well advanced and subject to early promulgation are: dyes and coal-tar products, sulphur and sulphuric acid, barium compounds, bleaching powder and other chlorine products, citric and oxalic acids, and botanical drugs. In earlier stages of preparation are: lactic acid, thorium nitrate, potash, wood distillation and its products, soap, glycerine and fatty oils, and paints and pigments. Other subjects will follow.

The first study was made on dyes and coal-tar products and this has now progressed so far that it is probable that the first official memorandum on a chemical group of products will be forthcoming within a few weeks' time. We shall reserve discussion until the complete report appears.

A great deal of information has to be asked for because changes are far too rapid to depend upon the U. S. Census; but by friendly co-operation with other departments of the Government much timely information is obtained and the work advanced. A very important report that is in preparation for the benefit of Congress is on the significant changes in chemical industry that have come about owing to the war, with especial reference to changes likely to have a permanent influence on international competition. Work along similar lines is in progress on the metal schedule.

It is hoped that manufacturers and merchants will present their appeals for aid or relief to the commission rather than attempt to spring undigested claims upon Congress at the last moment of debate. The temper of the national legislative body under its great pressure of work is such that neglect to inform the proper authorities of facts bearing upon tariff laws is likely to meet with impatience. Clever dodges are growing exceedingly unpopular.

Native Chinese Industries Discussed at Joint Chemical Meeting

At a joint meeting of the New York Sections of the American Electrochemical Society, American Chemical Society and Society of Chemical Industry held on March 1, two illustrated lectures were given on the native industries of China. Mr. H. K. Richardson, who spent four years in West China in charge of a Y. M. C. A. industrial school, described the production of placer gold, coal briquets, salt, matches, glass, indigo, sugar and tung oil. Mr. C. N. Laird of the Canton Christian College, South China, discussed and showed the primitive processes of making peanut oil and clay products.

Nitric Acid and Copper Ore

By GEORGE C. WESTBY

THE treatment of ores with nitric acid is not commonly resorted to even by the most daring of metallurgists. Occasionally, however, the exigencies of a situation cause the most cautious to look outside the boundaries of established practice, and sometimes a nitric acid process has seemed alluring.

Very little has been published in connection with the quest of those who have departed from the beaten metallurgical track, and sought to utilize nitric acid in ore treatment. This is the story of perhaps one attempt out of many unrecorded ones.

The force of circumstances, the nature of which it is needless to consider, induced an enterprising mining company to give the inventor of one of the nitric acid ore processes an opportunity to demonstrate the commercial value of the process.

Briefly, the method consists in a regulated addition of a batch of ground sulphide ore to warm, dilute nitric acid contained in a Pachuca-shaped vessel, called a digester. The heat developed by the ensuing reaction brings the temperature of the mixture up to around 100 deg. Cent. Steam is admitted to maintain the temperature between 80 deg. and 100 deg. Cent. as the chemical action in the digester gradually fails in energy with the weakening acid.

Compressed air admitted at the bottom of the digester agitates the mixture, and also supplies the oxygen necessary for the oxidation of the nitric oxide, which is developed by the action of the acid on the ore, to nitrogen peroxide.

The nitrogen peroxide produced in the digester together with the excess air is forced through a series of quartz-charged absorption towers partly filled with water. This results in the conversion of the nitrogen peroxide to nitric acid, which is again available for the treatment of fresh ore.

Disappearance of the colored nitrogen peroxide from the gases passing to the absorption towers as shown by a glass lantern inserted in the pipe line connecting the digester with the absorption system, marks the practical completion of the action of the acid on the ore. The contents of the digester are then discharged to the washing and filtering system.

Chemistry of the Process

The rationale of the process so far as it applies to the treatment of cupriferous pyritic ores is conveniently summarized in the following equations:

$$2FeS_2 + 10HNO_3 = Fe_2(SO_4)_3 + H_2SO_4 + 4H_2O + 10NO \quad (1)$$

$$3CuS + 8HNO_3 = 3CuSO_4 + 8NO + 4H_2O \quad (2)$$

$$6CuFeS_2 + 46HNO_3 = 6Cu(NO_3)_2 + 3Fe_2(SO_4)_3 + 3H_2SO_4 + 20H_2O + 34NO \quad (3)$$

$$6Cu(NO_3)_2 + 6H_2SO_4 = 6CuSO_4 + 12HNO_3 \quad (4)$$

$$6CuFeS_2 + 34HNO_3 + 3H_2SO_4 = 3Fe_2(SO_4)_3 + 20H_2O + 34NO + 6CuSO_4 \quad (3 \text{ \& } 4)$$

$$4NO + 2H_2O + 3O_2 \text{ (air)} = 4HNO_3 \quad (5)$$

$$4NO + O_2 = 2N_2O \quad (6)$$

$$N_2O_3 + H_2O = 2HNO_2 \quad (7)$$

$$3HNO_2 = HNO_3 + 2NO + H_2O, \text{ also} \quad (8)$$

$$2HNO_2 + N_2O_4 = HNO_3 + 2NO \quad (9)$$

$$2NO + O_2 = 2NO_2 \quad (10)$$

$$2NO_2 + H_2O = HNO_2 \quad (11)$$

The hypothesis is sometimes advanced that under the conditions of the treatment described it is not necessary to add as large a proportion of nitric acid to the ore as the quantity called for by the terms of equations (1), (2) and (3). The postulate is based on the inference that nitric acid would be largely regenerated within the digester, as the liberated nitric oxide mixes with the air and liquid spume in the space above the reacting ore and acid. It will be seen, however, from results of experiments given below, that this regeneration is insufficient to produce marked effects in extraction of further valuable metal from the ore.

Also with reference to equations (1), (2) and (3), we have illustrated the fact that the material subjected to treatment is preferably a sulphide ore containing sufficient combined sulphur to permit the formation of sulphate from all bases susceptible to attack. Excess of sulphur might be taken up by the addition of an oxidized ore, a deficiency must be remedied by the introduction of sulphuric acid or its equivalent.

Further, in connection with formulæ (1) and (2), the statement might be made that successful commercial application of this form of nitric acid process hinges largely on virtually complete evolution of sulphates in the reaction of nitric acid on the sulphides, for production of nitrates in appreciable quantities involves ultimate loss of this expensive reagent in the discharged tailings and in the solutions discarded from the precipitation system of the plant. An expression for a possible subsidiary reaction occurring simultaneously with equation (1) is

$$8HNO_3 + 2FeS_2 = 2Fe(NO_3)_3 + 2NO + 4H_2O + 2S_2 \quad (12)$$

Equations (4) to (9) inclusive refer especially to means of regenerating nitric acid from nitric oxide, air and water, and indicate the circuitous path traversed by a portion of the nitrogen compounds in the formation of nitric acid.

In the absorption treatment it is necessary to keep the cooled nitrose gases in contact with the water and air for at least five minutes, and this implies careful proportioning of the absorption system to the volume of gases we expect to treat. German and English practice has shown that when an adequately large mixing and tower system is provided, practically complete absorption with corresponding recovery of nitric acid is possible; however, even with the use of an end tower charged with an alkaline liquor, it is seldom commercially feasible to obtain a greater absorption than 97 per cent of the nitrose gases passing through the system. The commercial meaning of a 3 per cent loss of nitric acid in a regenerative process using nitric

acid as a solvent for cupriferous pyritic ores, is painfully apparent in estimates submitted in connection with the results of tests given farther on in this record.

Experimental Work with Laboratory Apparatus

Preliminary tests on the process outlined were made with a glass apparatus designed to treat two or three pounds at a charge. The apparatus consisted of the parts represented in Fig. 1. *A* is a closed ore-holder provided with a removable top through which ore may be introduced. The digester *B* is situated directly under the holder and the two parts are connected by a short conduit, in which the feeder controlling the flow of ore to the digester operates. Steam and air pipes connected with the bottom of the digester provide means for heating, agitating and oxidizing the mixture charged to the digester. The nitrose gases formed in the digester escape through the exit pipe, the cooling coil and lanterns *C* and *D* to the mixer and condenser *E*, thence, by the pressure formed within the digester

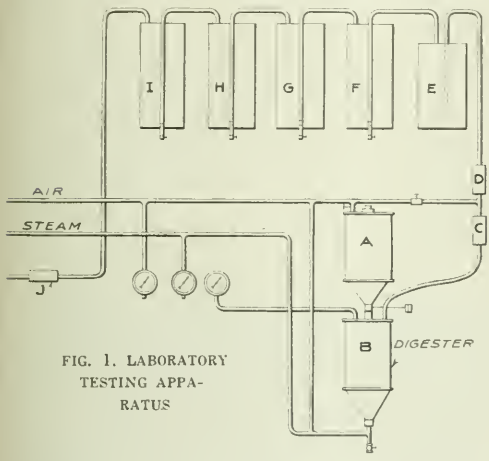

FIG. 1. LABORATORY TESTING APPARATUS

the gases are forced through the absorption towers *F*, *G*, *H* and *I* to the final discharge. As shown by sketch, an air-pipe connection is made between lanterns *B* and *D*. This arrangement provides a means for testing the completeness of the oxidation of NO to NO_2 by comparison of the depth of color when air is turned into the gas stream passing through the lanterns. The gages shown register air, steam and digester pressures.

Many of the results obtained from tests were vitiated by leaks which developed in most unexpected places as the pressure in the apparatus approached 10 lb. gage per square inch; but the tests submitted, in order to illustrate the general possibilities of the process, were selected because no leaks were detected after close inspection of the apparatus throughout the test.

Test No. 1

Analysis of Ore

	Per Cent
Al_2O_3	2.0
S	29.0
CaO	5.8
Cu	3.6
Fe	26.9
Insol	26.4

The gangue was garnetiferous with calcite present.

Estimation of acid required to treat the ore is based on equations (1), (2), (3) and (4), and consideration of sulphur (or equivalent sulphuric acid) required to sulphatize all the basic elements of the ore.

Assuming all copper in the ore and part of the iron combined with sulphur to form chalcopyrite ($CuFeS_2$), we have by equations (3) and (4) the factors Cu, Fe, S, HNO_3 and H_2SO_4 expressed in the ratios

$$378 : 336 : 384 : 2142 : 294$$

respectively, which gives when represented in per cent referred to the analysis and weight of the ore

Cu 3.6%, Fe 3.2%, S 3.65%, HNO_3 20.4% and H_2SO_4 2.8%.

Considering the balance of the sulphur combined with iron to form FeS_2, we obtain from the ratios derived from (1) the following expressed in terms of per cent referred to the analysis and weight of the ore:

Fe = (26.9 — 3.2 — 1.52) = 22.18%
S = (29.0 — 3.65) = 25.35%
HNO_3 = 124.53%
H_2SO_4 = 19.4%

Consequently we require (20.4 + 124.53) = 144.93% of absolute nitric acid as referred to the total weight of ore to be treated, to decompose the sulphide constituents in accordance with the equations given. Further, assuming the basic constituents of the gangue, such as iron, alumina and lime, to be readily susceptible to the action of the dilute sulphuric acid of the solution, we require for

1.5% Fe	a quantity of H_2SO_4 equivalent to	3.9% of wt. of ore
2.0% Al_2O_3	a quantity of H_2SO_4 equivalent to	5.7% of wt. of ore
5.8% CaO	a quantity of H_2SO_4 equivalent to	10.2% of wt. of ore
Total		19.8%

Finally then, considering all sulphur shown in the left hand member of the equations discussed, oxidized to sulphuric acid, we require for treatment of

$CuFeS_2$	a quantity of H_2SO_4 equivalent to	13.97% of wt. of ore
FeS_2	a quantity of H_2SO_4 equivalent to	58.18% of wt. of ore
Gangue	a quantity of H_2SO_4 equivalent to	19.80% of wt. of ore

or for sulphatizing all bases equivalent to 91.95% of wt. of ore

The total sulphur present as sulphide in the ore, oxidized to H_2SO_4 would yield a quantity of H_2SO_4 equivalent to 88.74% of the weight of the ore. Consequently we must add 91.95 — 88.74 = 3.2% of weight of ore of H_2SO_4 to complete the sulphatizing of the bases mentioned.

While it is evident that a slight excess of sulphuric acid also might be very useful in completing the dissolution of the ore and accelerating the extraction of the valuable metals, no H_2SO_4 was added in the preliminary tests in excess of that called for by the estimate derived in the manner given above.

In the test under discussion 554 grams of ore was charged to the digester. In accordance with the estimate outlined there should be added 788 grams HNO_3

and 17.73 grams H_2SO_4. However, only 1500 cc. of 1.24 sp. g. nitric acid was added containing 707 grams HNO_3. This was to insure maximum regeneration of nitric acid charged to the digester in order to determine the practical effect of possible regeneration within the digester and to neutralize the nitric acid.

General conditions during the test were as follows:

Feeding ore to digester, min.	60
Length of run, min.	94
Gage pressure at start, lb.	8
Gage pressure finish, lb.	10
Average temperature of mixture in digester, °C	64.6
Highest temperature of mixture in digester, °C	77
Lowest temperature of mixture in digester, °C	40
Temperature at finish, °C	56

Nitric acid recovery.	HNO_3 g
In absorption towers	484
In mixer or condenser	185
	669
Nitric acid losses.	
In solution discharged	41
Lost by discharge from absorption towers by difference	7
	48

	Per Cent of Original
Therefore available recovered acid was	93.4
Acid regenerated in absorption system	67.5
Equivalent HNO_3 in solution discharged	5.7
Equivalent HNO_3 lost as nitrose gases	0.9
Cu extraction (allowing for Cu in excess ore)	87.3

TEST NO. 2

Analysis of Ore

Al_2O_3	2.0
CaO	8.5
Fe	29.0
S	32.2
Cu	5.1
Insol	21.7

Expressed in terms of percentage referred to the weight of ore, sulphatizing of the bases requires for

	Per Cent S
Copper to form $CuSO_4$	2.6
Iron to form $Fe_2(SO_4)_3$	24.8
Lime to form $CaSO_4$	4.9
Alumina to form $Al_2(SO_4)_3$	1.9
Representing a total of	34.2

Sulphur supplied by ore is 33.2%. Sulphur deficiency to be supplied in the form of H_2SO_4 is accordingly 2.0%, equivalent to 6.1% H_2SO_4.

Based on equations (1), (3) and (4) approximately 161% HNO_3 is called for in the treatment of the ore.

	Grams
Weight of HNO_3 in 1500 cc. 1.26 sp. gr. acid charged to digester	782
Weight of ore charged	750
Giving an excess of	285

General conditions during the test were as follows:

Feeding 80-mesh ore, min.	44
Length of run, min.	70
Gage pressure, at start, lb.	6
Gage pressure, at finish, lb.	10
Average temperature of mixture in digester, °C	75
Highest temperature of mixture in digester, °C	87
Lowest temperature of mixture in digester, °C	40
Temperature at finish, °C	83

Nitric acid recovery.	HNO_3 g
In absorption towers	509
In mixer or condenser	187
Total	696
Nitric acid losses.	
In solution discharged	51
Lost in discharge from end absorption tower (by dif.)	35
Total	86

	Per Cent of Original
Therefore available recovered acid was	89.0
Equivalent HNO_3 in solution discharged	6.5
HNO_3 lost as nitrose gases	4.5
Copper extraction from ore	89.5

If the equations tentatively given as an expression of processes of this type are substantially correct, we should expect fairly close accordance between the figure representing the percentage recovery of nitric acid and that giving per cent of bases dissolved. It was found that a relationship existed even in tests where an excess of nitric acid was used, that tended to establish the fact that the treatment progresses in general accordance with equations (1), (3) and (4), and that the reaction expressed by (12) is not an important factor in the process.

The results of ten tests gave:

	Per Cent
Average nitric acid recovery	90.5
Average copper extraction	88.9

Some distillation of HNO_3 from the solution is indicated, but the acid brought into the absorption system by distillation cannot be of consequence, since the acid added to the digest is dilute and constantly decreasing in strength as the reaction of the acid on the sulphides proceeds.

In one or two tests excessive agitation projected a larger quantity of undecomposed acid into the condenser. The results of the second test given above are an example of this condition. An appreciable regeneration of nitric acid within the digester should become apparent by relative increase of the figure expressing the percentage of extraction of bases over that showing the recovery of nitric acid, but eliminating ques-

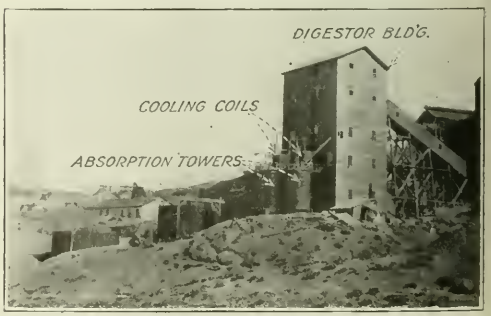

FIG. 2. EXPERIMENTAL UNIT FOR NITRIC ACID PROCESS

tionable results, in no test of the series did the results show a higher figure for extraction of base than that expressing acid recovery. It is conceivable that distillation and regeneration of acid might balance, but in view of the fact that the conditions in the digester do not coincide with the conditions necessary for effective absorption of NO_2 as given above, and the further fact that the distillation is necessarily small, there is reason for the conviction that regeneration in the digester is inconsiderable.

Comparative Cost of Nitric Acid and Leaching Processes

Before proceeding with a résumé of results obtained from the application of the process on what was expected to be a fifty-ton scale, we submit comparative estimate of cost between the nitric acid process and one in which roasting and sulphuric acid leaching are the main features of the treatment.

It will be noted that a high recovery of nitric acid is assumed, for it will be seen that a high recovery of acid is necessary if the process is to be considered at all as a commercially feasible proposition.

The cost given for air may seem high, but it is based on actual measurements of the air used in some of the tests and consideration of the air theoretically required as shown by equations (1) and (10).

We have from equation (1) the ratio:

$$2FeS_2 : 10NO = 240 : 300 = 1 : 1.25$$

Under standard conditions the weight of one cubic foot of NO is 0.082 lb. (nearly).

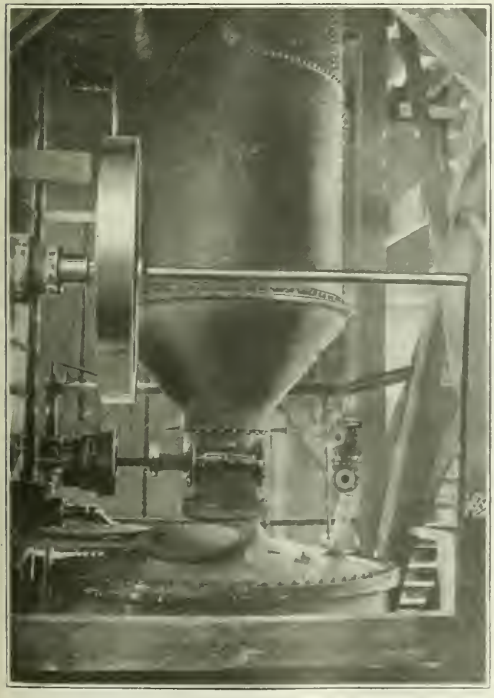

FIG. 3. LOWER SECTION OF ORE-HOLDER, FEEDER DRIVE AND TOP OF DIGESTER

$$\text{Then } \frac{1.25}{.082} = 15.24$$

Consequently in theory 1 lb. of FeS_2 develops with HNO_3 15.24 cu. ft. of NO, or at 68 deg. F. (20 deg. C.) and 24 in. barometric pressure, 19.62 cu. ft. NO.

From equation (10) 1 lb. of NO theoretically requires 0.532 lb. of oxygen in forming NO_2, calling for 2.32 lb. of air, or 48.2 cu. ft. of air at 68 deg. F. and 24 in. barometric pressure.

To compress and deliver 48.2 cu. ft. of air per minute at 30 lb. pressure requires about 4.1 hp., which is explanatory of the cost item for air.

Data assumed in consideration of nitric acid ore treatment.

HNO_3 manufactured at the mine at 3c. per lb.

Loss of HNO_3 = 2% of total added.

Copper recovery = 90%.

	Per Cent.

Analysis of ore—given in preceding estimate.

Leaching in tanks by percolation.

Copper recovery, 90%.

Estimated cost of treating one ton of ore by roasting and leaching:

Mining one ton of ore	$1.25
Roasting	1.00
H_2SO_4 required—300 lb. at ½c	1.50
Amortization and interest	.35
Crushing and grinding	.35
Handling tailings, pumping, etc	.05
Precipitation of copper	.65
Freight, selling, etc. (65 lb. Cu at 2c)	1.30
	$6.45
Credit 64.8 lb. Cu at 15c	9.72
Possible net	$3.27

The results of the laboratory tests of the nitric acid process were instructive, but unfortunately did not emphatically prove that the process was a striking improvement on methods of ore treatment which it was

designed to supplant. The promoters of the process, however, were of the opinion that the laboratory-scale tests proved nothing of what might be done with larger apparatus. They mentioned achievements in different fields with a large digester, stating also that a 40 per cent regeneration was a common experience with the special type they had worked with; moreover, they owned a complete 50-ton plant ready for installation. The mining company determined to allow the process company to proceed with the erection of their commercial unit.

Supplementary Test on Large Scale

The plant was made an adjunct of a dry-crushing mill and was similar in general arrangement to the small laboratory equipment already described. The digester was about 7 feet interior diameter and 14 feet high, and was lined with acid-proof brick set in acid-proof cement. The ore-holder was made of heavy sheet iron and was approximately 12 feet high and 7 feet in diameter. The condensation and absorption system consisted of two 3-in. aluminium coils made up with about 240 feet of pipe, and set in tanks supplied with circulating water; a condenser made from a lined sheet-iron cylinder placed inside a high wooden tank, through which cold water circulated; and a set of five absorption towers, four of which were 16 feet high and about 7 feet in diameter and the fifth in the series 16 feet high and 10 feet in diameter. Pipe connections were made with 2½-in. and 3-in. aluminium pipe and fittings. Solution pipes and fittings were made of duriron. The 1½-in. solution pump used was also made of that alloy.

In operation sulphide ore from the mill was diverted from a conveyor to a small bin situated above the ore-holder. Weighed batches of ore were drawn for each test from the bin to the ore-holder. Nitric acid or a mixture which might consist of a solution of nitric acid, sulphuric acid and nitre was run into the digester from a measuring tank. The solution was then heated by means of steam, which passed into the bottom of the digester through a rubber hose and duriron connections. After the solution had attained a temperature approaching 140 deg. Fahr. air was forced into the digester with the steam and the ore-feeder started.

In presenting the subjoined data it should be stated that the nitric acid was for the most part not added directly to the ore, but was developed indirectly in the solution in the presence of the sulphide ore by means of nitric and sulphuric acid. This method, however, was stated in the patent specifications to be equivalent to the use of nitric acid.

Two of the most successful tests are selected for illustration. The tests were controlled and carried out by patentees of the particular nitric acid process used, the company's representatives making duplicate tests at the same time.

Insol	69.7

Ratio of pulp to solution by weight 1.63.

Extractions:

	Per Cent.
Copper	67.2
Iron	71.4
Sulphur	67.4

Nitric acid recovery in towers plus loss through end 75.7 per cent.

Remarks:

The probability is strong that the difference between 75.7 and 67.4, figures representing total acid driven from digester and sulphur dissolved respectively, is an approximate measure of the quantity of nitric acid either distilled or mechanically carried into the absorption system.

The strength of the discharged solution in HNO was approximately 3 per cent. Action of this dilute solution on the excess sulphide present would doubtless continue, but the action is undoubtedly slow and there is more than a possibility that nitrogen compound such as N_2O may be formed in a large degree, as the acid weakens with sulphides in relative excess; these compounds would not be recovered in the absorption system.

TEST B

Ore Analysis

	Per Cent.
Cu	2.15
S	15.3
Insol	46.5
CaO	7.6
Al_2O_3	5.3
Fe	15.5

Ore Charge:

Ore charged to holder, lb.	3881
Ore left in at end of test, lb.	2271
Actual charge of digester, lb	1610

Note: Dry weights are given.

Nitric and sulphuric acids:

HNO added to digester, lb.	1735
HNO theoretically required (approx.), lb.	1231.5
Excess, lb.	503.5
Sulphuric acid charged, lb.	1400
Sulphuric acid required for bases and decomposition of NaNO	1372

Nitric acid recovery:

Recovered in towers, lb.	634.1
Recovered in condensers, lb.	93.1
Recovered, total, lb	727.2
Percentage recovery of HNO based on theoretical HNO_3 required	59.1
Percentage recovery of HNO plus end loss through absorption towers	62.46

Nitric acid losses:

Nitric acid in digester at finish as nitrates and free HNO_3, lb.	966.6
Nitric acid in excess of theoretical required, lb.	503.5
Nitric acid figured for treatment of unchanged sulphides, lb.	463.1
Nitric acid lost through end absorption tower discharge as nitrose gases, lb.	41.4
Percentage nitric acid lost through end absorption tower discharge as nitrose gases	3.36
Percentage nitric acid left in digester (of theoretical)	37.54

Discharged Solution:

Weight, 10,174 lb.

Cu = 0.24 per cent = 24.4 lb.

Fe = 1.72 per cent 175.0 lb.

S = 6.0 per cent = 610.0 lb. 610

457.2*

152.8 lb. sulphur derived from ore.

HNO = 9.60 per cent 19 lb. S approx. left in tailings in combination as $CaSO_4$

Contents of Original Ore

34.62 lb. Cu

246.33 lb. S

249.55 lb. Fe

From these results we obtain the subjoined figures:

Extractions:

	Per Cent
Cu	70.5
Fe	70.1
S	69.8
HNO	62.4 passing into absorption towers and condenser

Tailing Analysis:

Per Cent		
Cu	1.74	10.22 lb. by diff. which gives 587 lb. tails
Fe	13.3	74.55 lb. by diff. which gives 560 lb. tails
Insol	55.8	
CaO	5.2	
S	14.2	93.5 lb.

3.0 of above combined with CaO

The fact that the figure for extraction of bases is numerically greater than that for nitric acid recoveries (plus the fumes passing through end tower) gives reason for the belief that in this case some copper and iron are in the form of nitrates. And we may suspect the operation of a reaction as expressed by equation (12).

Temperature:

The temperature of the gases passing from the digester varied during active operation between 177 deg.

*Note 457.2 lb. S [illegible] H_2SO_4 to digester

Fahr. and 220 deg. Fahr. (thermometer wrapped outside of pipe).

Time:

Minutes preparatory heating digester solution	198
Minutes feeding ore	78
Minutes elapsing between first and last appearance of colored NO_2	135
Pressure in digester	18 to 20 lb.

Gas:	Per Cent NO_2
Entering (average of four determinations)	7.05
Exit (when strong color was apparent at discharge)	2.7

Steam:

Average gage pressure 41 lb.

The steam heated 10,886 lb. of solution from 70 deg. Fahr. to 150 deg. Fahr. approximately.

Heat added by means of admission of steam was consequently 870,880 B.t.u. (assuming Sp. heat = 1).

Considering 12,000 B.t.u. derivable from 1 lb. of coal —then we have the equivalent $\frac{870,880}{12,000} = 72.57$ lb. of coal, and allowing for radiation and other heat losses, we have 100 lb. of coal required for preliminary heating of the acid solution.

At ratio of 1:3 = pulp:solution, and assuming cost of coal at $6 per ton, the figures given indicate a heating charge of about 16c. per ton of ore.

Air:

Assuming 29 per cent of the ore to consist of FeS_2, then from equation (1) we have, by the action of HNO_3 on 1610 lb. of ore, in round numbers 583 lb. of NO. The latter compound in forming NO_2 calls for 311 lb. of oxygen or almost 1355 lb. of air. The volume under standard conditions of 1355 lb. of air is 16,800 cu. ft.

In the test under consideration air was used for oxidation 140 minutes continuously. This would be at the rate of $\frac{15,800}{140} = 120$ cu. ft. per min. under standard conditions, if the whole of the ore was dissolved in accordance with equation (1) and the whole of the oxygen in the air utilized.

We actually used approximately 414 cu. ft. per minute, which indicates nearly 300 per cent excess over the theoretical of 120 cu. ft.

To compress 414 cu. ft. per minute to 40 lb. by single-stage compression requires about 46 hp. through 144 minutes. This power therefore is necessary to effect the oxidation of the NO derived by the treatment of 1600 lb. of ore, in accordance with the conditions obtaining in the test. Under the same conditions 2000 lb. of ore would call for 69 hp. through 144 min. per ton of ore for oxidation of sulphides.

If power costs are at the rate of 15 cents per horsepower day, these charges for air would be $1.04 per ton of ore treated in the case under consideration.

Ludwig, Nev.

Metallurgical Renaissance in England.—An announcement from the Institute of Metals (British) states that the last year has witnessed a remarkable growth in the institute's membership—from 660 to over 860. It is expected, in view of the war-stimulated "metallurgical renaissance"—as it has aptly been termed—that the 1000 mark will be passed in the present year.

Rubber and Jelutong

A Review of the Evidence in the Recent Customs House Dispute as to Classification of Gums

By Frederic Dannerth

A RECENT decision of the Board of U. S. General Appraisers has drawn attention to a matter which has for some time engaged the attention of rubber chemists, more especially since the New York Rubber Conference of 1912. I have in mind an officially recognized, standard nomenclature for terms used in the rubber industry. I believe it was Mr. Frederic Hood of Boston who spoke in favor of this at the time of the conference, and gave the impetus to the later discussions. In 1915 the Rubber Committee of the American Society for Testing Materials recognized the desirability of such a list of official definitions, and a committee was accordingly formed, with the writer as chairman, for the purpose of recording definitions as they are understood in the rubber trade. In 1917 (April 1) this journal presented a tentative list of terms used in the rubber industry, together with definitions for these terms showing the meaning applied to them in the American rubber trade. This list may be considered fairly representative, as it was scrutinized previous to publication by representative rubber importers, manufacturers and their chemists.

One of the deterrents in the situation has apparently been the so-called factor of "good judgment." This, so far as I am able to discern, is a method of buying and selling wherein the seller feels sure that he is selling his merchandise at a comfortable profit and the buyer feels equally confident that he knows more about the goods than does the seller. We have here, as it were, a case of "guess as guess can." This tradition has been applied in a great measure to the problem of definitions for crude rubber and rubber products. Just as this so-called "good judgment" is giving way to laboratory methods of testing the *value* of raw rubber, so the loose use of terms in the buying and selling of crude and raw rubber is being abandoned. The American rubber industry is most certainly to be congratulated on the progress thus far made in both these problems.

At the annual meeting of the Rubber Association of America, in 1917, that society described, by name only, certain standard qualities of rubber. The chemical and physical properties of the four standard qualities are still left to the variable known as "good judgment." The standard samples are on file at specified places, but are available for optical inspection only. The committee in charge of these official terms felt that if it appeared desirable later on to go into the matter more comprehensively this could still be done.

The American manufacturers of rubber-goods to day fully realize that rational specifications are rapidly displacing the "good judgment" of the old type of buyer. This holds good for the man who sells crude rubber to the rubber-goods manufacturer, and it also holds good for the manufacturer who sells the finished rubber product to a railway or a municipality. I am inclined to believe that many legal cases based on breach of contract would be impossible if buyer and seller would have a care to define the chemical and physical properties which the merchandise should pos-

sess. In a like manner many disputes arising from the assessment of duties by the Collector of Customs would probably be avoided if the importers themselves had a clear knowledge of the chemical and physical properties of the merchandise which they import. Bigger than all of this is, of course, the desire on the part of the importer to abide by the letter as well as the spirit of a tariff act.

One of the immediate results of this lack of definitions in the American rubber industry was the jelutong (or pontianak) case, heard in New York City in February, 1917. An importing firm had been called upon by the Collector of Customs to pay a duty of 10 per cent ad valorem on pontianak, it having been classified as *a non-enumerated, unmanufactured article,* under paragraph 385 of the Tariff Act of October 3, 1913. The importers claimed that it was entitled to free entry as crude rubber under paragraph 513.

In presenting the evidence for the consideration of the court the importers aimed to show that jelutong is known throughout the United States, and was known, on and prior to Oct. 3, 1913, as *crude India rubber.* They further expected to show by persons who manufacture articles out of it that it is known to them as rubber, used as rubber, and has no other use than as rubber. Some of the evidence presented was interesting, to say the least, and may serve to enlighten some of our rubber manufacturers. For example, one witness for the importers stated that jelutong was not used as a filler or an adulterant in a rubber compound. The inference here is that jelutong must belong to the class of materials known as rubbers. This is, of course, a lapsus, as it is commonly known that the substances which enter into a rubber compound are classified under possibly a dozen different heads, among which are adhesives, fillers, adulterants and rubber. The fact that jelutong is neither a filler nor an adulterant is not conclusive evidence that it is a rubber. The same witness stated that he knew of no substance other than rubber which could be used in a rubber compound to hold the several ingredients together. This hardly corroborates the experience of successful factory superintendents. The witness also stated that it is generally understood (in Boston and in New York, by the trade that engages in it) that jelutong is included in the commercial designation of rubber. If this be true, it would be well for dealers in rubber to take note of this remark, as it may enable them to deliver jelutong on any contract where "rubber" is specified.

Although the importers claimed that jelutong has for some years been known as crude India rubber, it was repeatedly shown in the testimony that the phrase "rubber" is rarely, if ever, used in buying and selling. The phrases that are used are "smoky sheets," "crepe," and the like, but the phrase India rubber, or the word rubber, is seldom used. The principal witness for the importers stated that jelutong is known to everybody in the trade, discussed and known by all users as rubber. On cross-examination it was, however, brought out that the matter had never been discussed by the witness with other dealers in rubber. One witness, who described himself as a compounding chemist, stated that the use of any of the various kinds of rubber will give to a compound the same qualities that the jelutong gives to the compound; that caoutchouc (the rubber hydrocarbon) is the prevailing ingredient of jelutong. This testimony was offered in the face of the fact that jelutong, when washed and dried, consists of approximately 25 per cent rubber hydrocarbon and 75 per cent resins.

One witness who testified to certain chemical facts in the case stated: "There are some nine hundred odd rubbers coming into the port of New York at different times." This is certainly a very generous estimate of crude rubber varieties, but rubber importers will accept this with considerable hesitation. He also testified, quite correctly, that rubber is the one material which shows both plasticity and elasticity. Fortunately for the importers, he forgot that pontianak (or jelutong) possesses little or no elasticity. It is for this latter reason that a considerable percentage of all chewing gum can be made of pontianak in whole or in part.

Owing to the pressure of bigger issues it was apparent that the Government did not secure the testimony of those who use jelutong, and so it was that some odd statements crept into the record without contradiction. Thus we find it stated that "jelutong is used in the same way and for the same purposes that other grades and qualities of rubber are used." In view of such testimony, the court had no choice but to sustain the protest and admit jelutong as "rubber." The whole case is of more than passing interest, and I have therefore taken some pains to bring to a focus our present knowledge concerning the character of the gum in dispute.

Trade Customs, Character and Uses of Jelutong

In one of the trade journals we find in September, 1913, that separate statistics are presented for "gutta jelutong" and for "India rubber." This makes a careful distinction between the two gums, and this distinction was never criticised.

Of all the jelutong produced in the East Indies in 1911 and 1912, a considerable portion was passed through a manufacturing process at the Goebilt-Sarawak Works of the United Malaysian Co. The process was known as deresination, and the products obtained as a result of it are: jelutong rubber (as residue) and jelutong resin (as extract). Samples of this jelutong rubber were exhibited in New York City in 1912 at the Rubber Conference, under the name "Malaysian crepe." (See Schidrowitz: Rubber, page 110, published 1911.) In May, 1910, that chemist made an inspection of the plant at Goebilt, Borneo, and later published his observations. The United Malaysian Company in 1912 published a pamphlet in which they recommend the use of jelutong in such proportions that 100 lb. of the compound or dough contains not more than 7 lb. of jelutong.

Potts, in his book, page 34, states: "An example of a highly resinous rubber is Malay crepe. This is obtained from jelutong, a *gum* containing (in its wet state) only about 10 per cent rubber. This is derived from the latex of *Dyera costulata.*

Jelutong cannot be used in the same way as rubber. The best results in vulcanization are obtained when the rubber used contains not more than 8 per cent resins. Experience shows that substances containing 15 or 20 per cent resins cannot be vulcanized in the usual manner.

Jelutong is a mixture of resins and rubber, and so is the commodity known in commerce as crude rubber, but the resins in jelutong have entirely different properties than have the resins of Hevea and similar rubbers. For example, the unsaponifiable matter is approximately 15 per cent in Hevea resins and 100 per cent in jelutong resins.

The specific rotary power is + 50 degrees for jelutong resins and zero degrees for Hevea resins.

The fact that jelutong is used in the United States principally by manufacturers of rubber products cannot affect the case, since there are numerous materials of which the same might be said (*e.g.*, vulcanized oils).

The characteristic which jelutong possesses which gives it its peculiar value is this: It renders the compound tacky or sticky, so that the compound can be used for binding together two surfaces, such as two layers of cotton duck used in building auto tires. Rubber itself does not possess this sticky character. These properties make it absolutely impossible to use jelutong in certain compounds. For example, no skilled chemist, versed in the art of rubber compounding, would use it in making auto tire treads or elastic bands or erasers. It is likewise a matter of common knowledge that no useful compounds can be prepared using jelutong and sulphur and omitting rubber. The fact that jelutong, after washing and drying, contains about 75 per cent resins and 25 per cent rubber, makes it undesirable for exclusive use as a substitute for rubber.

Proper Classification of Jelutong

A more correct classification for jelutong would be "a resin occurring naturally admixed with rubber, in the approximate proportion of 3 parts resin and 1 part rubber hydrocarbon."

Jelutong has been used successfully in the manufacture of chewing gum in the United States. Not merely the resins, but the entire material (after washing and drying) has been used.

Rubber of commerce is a material which, when admixed with sulphur in suitable proportions, can be vulcanized into a product having distinct properties of elasticity and tensile strength. The products so obtained can be applied to useful purposes. Jelutong does not comply with these requirements.

In order to produce useful products it is not necessary to mix or blend various rubbers. If in a given recipe, no other organic material but washed and dried Hevea rubber be used, a useful vulcanized product can be produced. If in a given recipe no other organic material excepting washed and dried jelutong be used, no useful product can be produced which will in the slightest degree resemble that obtained from the Hevea rubber.

Hevea rubber, plantation crepe, and Para rubber are terms well known in the American rubber trade. In order to obtain from jelutong a product resembling these it is necessary to put it through a manufacturing process known as deresination.

Hevea rubber is a material commonly included under the term rubber. It can be converted into useful products by mixing it with, say, sulphur and zinc oxide, and subjecting the mixture to heat while under pressure. Commercial jelutong cannot be converted into useful articles in the same manner. It has, to my knowledge, never been used exclusively in the production of commercial rubber goods. Whenever it is used in a rubber compound it is used in conjunction with some variety of rubber.

The amount of washed and dried jelutong which can be used in a rubber compound to produce useful products is limited to about 7 per cent.

It is my opinion that no manufacturer would be willing to accept jelutong, balata or guttapercha as a good delivery if he had ordered rubber.

(The first protest heard has been decided adverse to the Government, but new evidence having been gathered by the Department of Justice, a new case was prepared, and heard in December, 1917. No decision on the second case has been handed down at this time.)

The Rubber Trade Laboratory,
Newark, New Jersey.

Saving Ammonia Urged.—The Food Administration to-night issued an appeal to the owners and operators of ice-making and refrigerating plants to take every possible precaution against waste and leakage in their use of ammonia.

As a means of effecting ammonia savings owners and operators of plants were urged to institute a bonus system by which employees would be rewarded for effecting economies. Each plant will be required to report on the first of each month exactly what it is doing in saving ammonia.

"During 1918," the announcement said, "the Government should have for munitions alone 20,000,000 lb. of ammonia more than it is possible to make by working all plants in this country to capacity.

"This shortage will be greatly increased by the ammonia that will be furnished ice-making and refrigerating plants, but it is hoped that by appealing to the patriotism and the sense of all ammonia users and urging them to stop all waste and leakage, the usual consumption may be curtailed to such an extent as will permit at least the most efficient plants to run, particularly where natural ice is not available."

Releasing Shipping by Developing Our Mineral Deposits.—Secretary Lane has asked Congress for a special appropriation so that a large force of metallurgists can be set to work on the necessary changes in practice to use lower grade manganese ores, and that geologists and engineers can be employed to develop deposits of materials in this country which are now imported. In this manner Secretary Lane believes considerable ship tonnage can be released to carry food and supplies to France. The minerals most needed are nitrate, pyrites, sulphur, manganese, graphite, tin, mercury, potash, tungsten, antimony, chrome, magnesite and mica.

Payment of United States Patent Office Fees on Enemy-Owned Patents.—The War Trade Board has authorized the payment of United States Patent Office fees requisite for the filing, prosecution, registration and preservation of patents, trade-marks, prints, labels, or copyrights, of an "enemy" or "ally of enemy" by any person within the United States, where such person is the holder of a power of attorney granted by such "enemy" or "ally of enemy"; provided, however, that when such fees are to be paid from the funds of an "enemy" or "ally of enemy" in the United States, such payment shall be made subject to the approval of the Alien Property Custodian.

Recovering Ammonia at Tar-Distilling Plants

BY CLARENCE R. WOODWARD

ALTHOUGH it has long been known to tar distillers that a certain amount of ammonia is present in the water contained in ordinary coke-oven, gas-house or vertical-retort tars, the large manufacturers of this country have not up to recently considered that its recovery, if it could be effected, would be profitable to them. This opinion has probably been due to the fact that very little has been done in the way of experimenting to find the actual state in which the ammonia is present, its strength or the possibilities of recovery.

In the past two years the writer spent considerable time working on this subject at one of the plants of probably the largest of the tar distillers in the United States. The results obtained show that not only can ammonia be easily recovered, but that due to many favoring circumstances connected with the character of the equipment of a distilling plant, its recovery at these particular plants can be accomplished very profitably.

Sources of Ammonia

At the tar works there are two sources from which ammonia can be recovered; the liquor which settles out on the top of the crude-tar storage tanks and the liquor which comes over with the light oil in the process of distilling the tar. As the storage tanks are both filled and emptied from the bottom, this liquor settling on top of the tanks is commonly allowed to accumulate undisturbed until such time as the amount begins to take valuable storage space, when it is run to waste. The distilled liquor will be shown to be by far the most profitable source, due to its great volume and strength; but, as is the case with the settled liquor, it has usually been allowed to run to waste. It will be the purpose of this article to show how these liquors can be converted into a profit for the tar distiller.

At the particular plant at which the experiments to be described were made, the coal tar received in the course of a year consisted of about 9,000,000 gal. coke-oven tar; 4,000,000 gal. gas-house tar and 600,000 gal. vertical-retort tar. About two-thirds of this tar was distilled at the plant, the remainder being disposed of in a crude state for road-building purposes, under trade names tending to disguise its true composition.

Laboratory Tests

Before any large-scale operations were attempted, laboratory tests for ammonia were made on the water settling on the top of the storage tanks and on the water distilled from the different kinds of tars in the laboratory. The results given are expressed in ounces of ammonia per gallon of liquor and also in the percentage of anhydrous ammonia, the percentage being obtained by dividing the number of ounces per gallon of liquor by 3.88.

Tests of the liquor settling out from the tar in storage are given in Table I.

TABLE I—LIQUORS SETTLING ON TARS

Tank No. and Class of Tar	Volatile Ammonia, Oz.	Fixed	Total Ammonia, Oz.	Per Cent Ammonia
No. 2 coke-oven	1.41	4.39	5.80	1.50
No. 3 gas-house	.705	1.77	2.48	.64
No. 11 gas-house	.82	1.58	2.40	.62
No. 12 gas-house	.69	2.22	2.81	.73
No. 22 vertical-retort	No water settled out.			

An examination of the liquor distilled in the laboratory from each of the three different classes of tar, coke-oven, vertical-retort and gas-house, showed an *average* strength as follows:

TABLE II—LIQUORS DISTILLED FROM TARS

Class of Tar	Strength Ammonia from Laboratory Sample, Oz.	Total Ammonia, Per Cent
Coke-oven	9.76	2.52
Coke-oven plus NaOH	12.1	3.12
Gas-house	2.81	.73
Vertical-retort	8.5	2.19

In the distillation of these tars the condenser was kept at all times absolutely cold, so that never was there any danger of ammonia loss. Under these conditions the strength of the liquor obtained represents the maximum that can be recovered from these tars in practice. The second test with NaOH was made for the purpose of seeing if the fixed ammonia in the tar could be broken up in the process of distilling.

The results of the experiments on the settled liquor indicated that with the exception of that on the coke-oven tar the strength in ammonia was very low. In fact, were it not possible to mix them with stronger liquors, recovery of the ammonia contained in them would not be practicable regardless of the volume available. It should be noted that about 70 per cent of the ammonia in this liquor is fixed and would necessitate using lime in the process of concentrating.

The water distilled from the tar, however, is found to be considerably stronger in ammonia than the water separated from the tar on standing, and suggests very profitable recovery.

The great difference in the strength of these two classes of liquor is noticeable, particularly in the tests of the water from the coke-oven tar, which contains 5.80 oz. ammonia in the settled liquor and 9.76 oz. in the distilled liquor. This is probably due to evaporation of ammonia from the surface of the water in the storage tanks, an action which takes place to a greater or less extent, according to the heat of the tar and to the surface exposed to the air, and which causes a smaller amount of NH in the settled liquor. The fact that the tar itself contains some ammonium compounds aside from those in the water with which it is intimately mixed causes a corresponding increase in the amount of ammonia in the distilled liquor.

It is rather remarkable, however, that the water distilled from the coke-oven tar should contain 9.76 oz. of free ammonia while the water separating from the same tar on standing contains only 1.41 free ammonia.

The explanation is that the distilled liquor contains only free ammonia for the reason that when the tar is distilled the free ammonia passes over with the water and the fixed ammonia remains behind. In the settled liquor the free ammonia has evaporated from the causes mentioned above.

The result of the test with caustic soda indicates that an additional amount of ammonia may be recovered through the breaking up of the fixed ammonia remaining in the tar. It was not, however, considered worth while to try out this test on a large scale in view of the difficulties likely to be encountered through the action of the caustic on the tar.

Large-Scale Tests

Ammonia tests were now made on water obtained from the distillation of tar on a large scale, 10,000-gal. direct-fired stills being used. In the making of road-building material and pitch it is customary at this plant to mix coke-oven tar and gas-house tar in about equal proportions. Most of the tests, therefore, were made on the water distilled from such mixtures. However, to make the experiment more complete, a special still of straight coke-oven tar and a still of vertical-retort tar were run to fuel pitch for the purpose of obtaining the liquor from these particular tars. The water was caught in the usual 100-gal. drums, from each of which a sample was taken to be tested for its ammonia content. During the time the water was coming from the still the condensers were kept a little cooler than is usual when no attempt is made to recover ammonia. The average of several tests on the tar mixtures is given in Table III.

Table III—Ammonia Liquor from Mixture of Coke-Oven and Gas-House Tars

Tub No.	Total Ammonia, Oz.	Total Ammonia, Per Cent
1	11.50	2.96
2	5.80	1.49
3	3.90	1.01
4	1.90	.49
5	1.60	.41
6	1.17	.30
7	2.90	.75
	28.77	Av. 1.058
	Av. 4.11	
(Average of first 3 tubs, 7.07 oz., or 1.82 per cent.)		
Liquor from Coke Oven Tar	9.52	2.45
Liquor from Vertical Retort Tar	8.25	2.13

The strength of the liquor from these last two tars is found on comparison to differ slightly in strength from the tests of 9.76 oz. and 8.5 oz. obtained from the same tars in the laboratory. However, I believe the difference is no greater than should be expected in view of the necessarily great variation in the two methods of distilling and sampling.

The ammonia in all of these distilled liquors was found on testing to be approximately 99 per cent free and 1 per cent fixed. The small amount of fixed ammonia in the liquor is probably due to combinations made with the gases in the condenser, or with salt water which may have leaked through the condenser coils. The condensers are cooled with salt water.

It is interesting to note that in the results of the tests of liquor from the distillation of the mixed tar, the last pan, or tub, is stronger in ammonia than the three preceding it. This fact was rather puzzling at first, but I finally judged it to be due to the formation of NH_3 from the fixed ammonia $(NH_4)_2(SO_4)$ at high temperature.

$$(NH_4)_2SO_4 = NH_3 + NH_4HSO_4$$

According to Bloxom this breaking down begins to occur about 100 deg. C. and is complete about 300 deg. C. The temperature of the tar is usually about 160 deg. C. in the still as the last of the water is being removed.

Liquor Recovered in Practice

In order to ascertain if this ammonia liquor could actually be recovered without loss in practice, an 18-day test was run, during which time the liquor from all the stills instead of being allowed to run to waste was dumped into ground tanks and from there pumped into a storage tank holding about 5700 gal. When full, this tank was emptied, several samples being taken of the liquor as it ran from the bottom. In this test the liquor obtained was subject to some contamination from rain-water and from salt water dripping from the condensers, but the amount was not sufficient to affect the results materially. The tests given in Table IV are the average of the several samples taken from each tank.

Table IV—Analysis of Conserved Liquor

Tank No.	Gross Gallons Water	Ounces Ammonia Per Gallon
	4,982 { Not included	4.63
	5,734 { in total	4.01
1	5,734	3.84
2	4,892	4.88
3	5,734	3.94
4	5,358	4.07
5	5,734	4.46
6	5,640	2.77
7	5,295	3.95
8	3,290	5.12
	41,767	Average 4.17
	Tar 2,053	
	39,716 net gal. water for 18 days	

This water was all taken from mixtures of gas-house and coke-oven tars, and from the figures obtained it is evident that if care is used to prevent evaporation there is very little loss to be anticipated in recovering the ammonia. The average test of 4.17 oz. agrees very closely with the average strength of 4.11 oz. in the liquor as it is given off from the still and before it is dumped into the ground tanks.

The composition of the distilled liquor, containing as it does 99 per cent of its ammonia in a free state, constitutes a most favorable condition for concentrating for the reason that no lime will be required. Not only is considerable expense thus saved, but a troublesome step in concentrating is eliminated.

From the experiments made, it appears that the bulk of the liquor recovered at the stills when the usual tar products are being made will average 4.11 oz. strength, a liquor considered workable, especially in view of the fact that ammonia is in a free state and to the circumstance of cheap steam and water being always available at the works. Should it be found desirable, however, to obtain a stronger liquor at the expense of the total ammonia recovered, it is only necessary to eliminate the last few tubs of weak liquor. A strong ammonia liquor will always be obtained when straight coke-oven and vertical-retort tars are distilled.

Estimate of Profit

Records of the plant show that the total amount of water distilled from the tar in the course of the year

averages about 700,000 gal. The water settling out of the coke-oven tar in the course of a year is 76,000 gal. and that on the gas-house tars 256,000 gal.

Assuming all the ammonia concentrated to a liquor of 20 per cent strength, which has at this time a value of about $0.10 a pound at the works, the total amount and value would be at this plant:

Liquor settling on coke-oven tar:

76,000 × 8.35 × 15% = 9,520 pounds ammonia

Liquor settling on gas-house tar:

256,000 × 8.35 × .665% = 14,220 pounds ammonia

Distilled from tar:

700,000 × 8.35 × 1.058% = 61,840 pounds ammonia

Total ..... 85,580 pounds ammonia

Total value of ammonia, $0.10 × 85.580 = $8,558.

If any considerable amount of coke-oven tar or vertical-retort tar is distilled without admixture of gas-house tar, as is the case when ordinary fuel or briquet pitch is made, the amount of ammonia recovered will be greatly increased.

The only apparatus required in addition to that present in all distilling plants is an ammonia concentrator for concentrating the weak liquor, a few small tanks and a little additional piping. The same pumps and pump lines used for oil can be used for handling liquor, cheap steam is, of course, available and the labor, which is usually a small item in concentrating particularly when no liming apparatus is used, can be accomplished by the regular stillmen and the hiring of extra help avoided.

The cost of the concentrator, together with the tanks and including the labor of setting up, would be about $4,000. The operating cost of concentrating the liquor per pound of ammonia recovered is estimated in Table V:

TABLE V—COST PER POUND AMMONIA

Steam	$0.0066
Labor and supervision	0.0030
Lime	0.0005
Repairs, paints, etc	0.0010
Interest and depreciation	0.0059
Contingencies	0.0030
	$0.0200

The total value of the ammonia being approximately $8,558, and the cost of recovering $1,712, a profit of approximately $6,746 a year is indicated at this plant.

It is not necessarily true that the above results would be duplicated at every plant distilling similar amounts of tar, for, as is well known, the quantity of ammonia present in a tar will vary with different methods of recovering tar at gas works and with kind of coal used in these plants. It is believed, however, that the results will not be materially different from those cited except in plants where the tar is bought already dehydrated.

In the particular plant where these experiments were made the coke-oven tar secured by the distillers is made from New River coal and the vertical-retort tar from Westmoreland coal. The gas-house tar represents the average of 30 or more different tars obtained from perhaps as many different coals. The company appropriated $4,000 to this plant to cover the cost of installing the ammonia concentrator and the other necessary apparatus and if it proves successful they expect to instal a concentrator at their other plants. At the present time it should make a very profitable investment.

A Gas Dilatometer for Ascertaining Decomposition Points

Determination of the Decomposition Points of Cane Sugar, Dextrose and "Soluble Starch"

BY WILLIAM C. MOORE AND J. B. DAVIES

DURING a recent investigation in this laboratory it became necessary to determine the decomposition points of a number of organic materials. As the apparatus devised for this purpose has served us so well, it was thought that a description of it would be of interest.

In its essentials, the arrangement we made use of consists simply of a glass decomposition bulb which is immersed in a suitable heating bath; an outlet tube containing a horizontal expanded portion which serves as a combined air condenser and receiver for volatile substances distilled out of the material being studied, and a mercury manometer with a scale attached to measure the pressure developed.

The construction details are easily seen in Figure 1.

The heating chamber *A* is conveniently made from an 8-in. test-tube, to the upper end of which is sealed the riser *B*. The horizontal bulb *D* which serves as an air condenser can likewise be made from an 8-inch test-tube. The mercury-filled manometer is shown at *E*. The shorter tube of this manometer is about 810 mm. long; the longer, with the open end, about twice this length. A thermometer is used for measuring the temperature of the condenser *D*.

In making a run, an appropriate quantity of the substance to be decomposed is weighed into a small glass tube *G*. This tube is placed in an 8-inch test-tube, the latter drawn down to a neck and sealed onto a short piece of glass tubing which serves as the riser *B*. This is then sealed to the rest of the previously assembled apparatus just below the T. The outfit is now ready to be placed in position with the bulb *A* completely immersed in the heating bath. Sufficient clean, dry mercury is introduced into the manometer to form a column in the shorter tube, at least 760 mm. longer than that in the open tube after exhausting. In introducing the mercury, air bubbles can be dislodged by a piece of iron wire moved up and down in the open tube. This

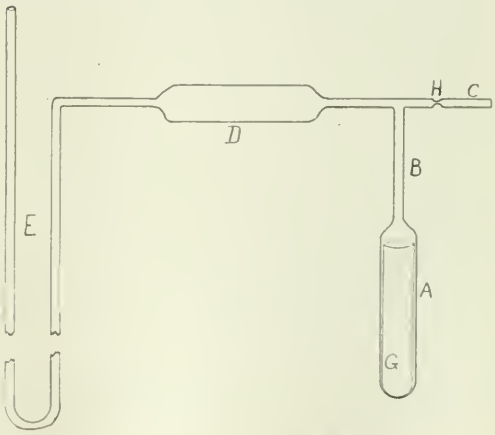

FIG 1. APPARATUS FOR DECOMPOSITION POINTS

wire must be long enough to reach the bend of the manometer.

The apparatus is now exhausted to a barometric vacuum through the outlet *C* and sealed at the constriction *H*. When all is ready the bulb is heated at a definite rate, readings being taken at regular intervals of the temperature of the heating bath, the temperature of the condenser, the difference in level between the mercury columns and of the barometric pressure. The total pressure within the apparatus is easily obtained by subtracting the difference in manometer levels from the barometer if the pressure is less than atmospheric,

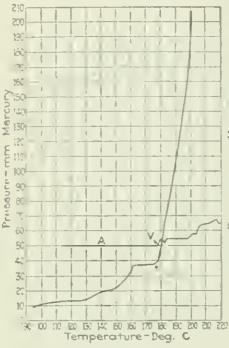

FIG. 2

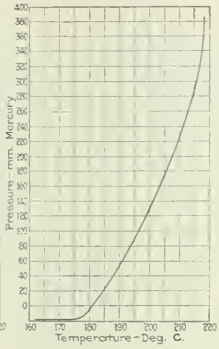

FIG. 3

or by adding these two quantities when the pressure is greater than the barometer reading. These pressures are plotted against the corresponding temperatures. In those cases where decomposition occurs, due to a permanent gas being formed by an irreversible reaction, the curve will show a sharp upward bend very similar to those shown in decomposition voltage curves.

If the condenser tube is not shielded from the heating bath, the temperature within it may rise to a high value. Where water is given off, the vapor pressure of the water within this part of the apparatus can readily be found from tables of vapor pressure of this liquid at different temperatures. This value may be subtracted from the total pressure to get the actual pressure of the permanent gas. However, proper shielding keeps the condenser tube at a fairly constant temperature which is approximately that of the room, in which event the vapor pressure of the water need not be taken into account since we are interested only in the singular points on the curve and not in the actual magnitude of

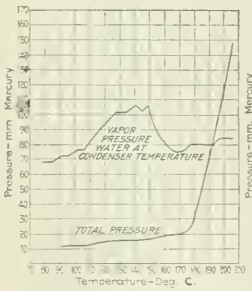

FIG. 4

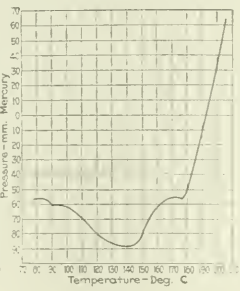

FIG. 5

the pressures developed. In some cases the rapid evolution of gas from the decomposing material will heat the condenser bulb also; this is shown on curve A* of Fig. 2 (Point V).

Working in the manner just outlined, the decomposition points of cane-sugar, dextrose and soluble starch were ascertained. In this case, the rate of heating was at about 1 deg. C. per minute up to 150 deg.; a little slower above that point. The heating bath was a large pail of paraffin which was continuously stirred by a paddle actuated by a motor.

Table 1 gives the summarized results. Figures 2 and 4 are the pressure curves obtained on two runs with cane-sugar. Figures 3 and 5 respectively are the corresponding curves after correction had been made for the water vapor in the apparatus. In Figure 5 it is possible that the contents of the condenser were not at as high a temperature as the outside thermometer showed.

TABLE I

DECOMPOSITION POINTS

Material Used	*Decomposition Point*
Cane Sugar	178 deg. C.; 177 deg. C.
Dextrose	177 deg. C.
Soluble Starch	214 deg. C.

Mercury in glass thermometer used.

The rate of heating is very important. Thus, at the slow rate of heating of 5 deg. per hour, cane-sugar decomposed at 155 deg. C., while soluble starch broke up at 185 deg. In these latter cases a Hoskins furnace up-ended was used as a large air bath.

This lowering of decomposition point by a decrease in the heating rate may be explained in this way; at a slow rate of heating, the sugar or starch molecules undergo some internal change which results in a less stable compound than the original sugar or starch being formed; while at a rapid rate, sufficient time does not elapse for such a change to occur.

Another possibility is that with very rapid heating (as at the rate of 1 deg. per minute) the material becomes superheated before decomposition occurs. With a number of other materials a similar elevation of the decomposition point was noted when the rate was changed from 5 deg. to 10 deg. per hour; this would indicate that with the 1-deg.-per-minute rate, the phenomenon is not due to delay in the decomposition material reaching the temperature indicated by the thermometer.

In order to correlate these results, work on other carbohydrates is planned.

A preliminary experiment, just completed, shows that a good quality of quantitative filter paper, when heated at 10 deg. per hour, did not exhibit a very sharp decomposition point; the evolution of gas began slowly at 143 deg.[1] There was some indication of a break at 185 deg. and a little sharper break at 204 deg. This material will be further investigated.

Research Laboratory,
National Carbon Co., Inc.,
Cleveland, Ohio.

*Curve A shows the vapor pressure of water at the condenser temperature.

[1]Hollings & Cobb (*J. Gas Lighting and Water Supply*, 132, 24, 1915; *J. Chem. Soc.*, July, 1915) have made a thermal study of the carbonization process. Altho they state that they attach no importance to the indications of their differential thermo-couple below 200° C., yet the curve they show for cellulose indicates that there is a gradual but considerable decomposition of this material, extending from a little under 150° C. up to 200° C.

The Physical Properties of Copper and the Factors by Which They Are Affected—III.

By Paul D. Merica
Division of Metallurgy, U. S. Bureau of Standards

(*Continued from page* 195)

Physical Properties at Higher and Lower Temperatures

1. Electrical Conductivity

Northrup (54) has determined the electrical resistivity of a sample of high conductivity copper from 20 deg. to 1450 deg. His curve is reproduced in Fig. 17.

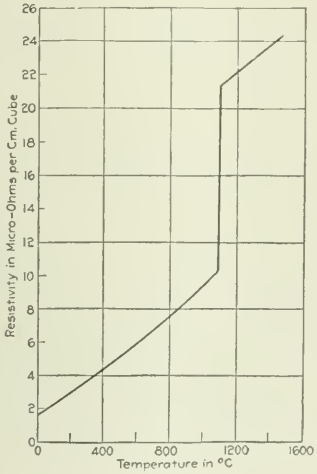

FIG. 17. THE ELECTRICAL RESISTIVITY OF COPPER AT HIGHER TEMPERATURES (54)

Dewar and Fleming (161) have determined in terms of platinum resistance temperatures the resistance of copper at low temperatures, using an electrolytic copper, drawn into wire without melting or heating, but subsequently annealed in hydrogen. Their results are as follows:

Temperature, Deg. C, Calculated By Dickson (162)	Temperature on the Platinum Resistance Scale	Resistance of Copper, Ohms (Meter, mm²)
201 7		0 029269
0. 55		0. 015639
−39. 4		0. 012975
−81 9	−78	0. 010243
−197. 1		0 002887
−206	−223 2	0 001436

2. Mechanical Properties

The mechanical properties which have been investigated at higher temperatures are chiefly those determined in the ordinary tensile test. Such determinations are complicated by several factors; the results are dependent upon the rate of loading and on the atmosphere in which the tests are carried out. It is not, therefore, surprising to find considerable variation in the results of different observers. An idea of the range of results may be obtained from Fig. 18, in which ultimate tensile strengths and elongation in 2 in. are plotted as a function of temperature at which the tests were made.

Bengough and Hanson (152) come to the following conclusions:

(1) "The nature of the atmosphere has an important influence on the results of tensile tests at high temperatures. An oxidizing atmosphere gives high ductility (at least with B.S. copper)at high temperatures.

(2) The existence of a range of low ductility in the neighborhood of from 250 deg. C. to 450 deg. C. is confirmed.

(3) Oxygen and arsenic lower the ultimate strength and increase the ductility at high temperatures." This last deduction is perhaps not in accordance with the well-known fact that arsenical copper softens upon annealing at higher temperature than pure copper. However, the yield point, not the ultimate strength, determines the latter characteristic.

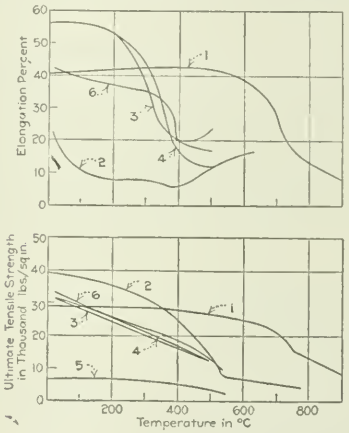

FIG. 18. EFFECT OF HIGH TEMPERATURES ON MECHANICAL PROPERTIES OF COPPER

Curves 1 and 2 (152) are for annealed electrolytic copper (oxygen, 0.08%; arsenic, 0.003%; iron, trace), and rolled arsenical copper (oxygen, 0.13%; arsenic, 0.13%; iron, 0.02%; lead, 0.10%; tin, 0.08%) respectively. The former was tested in air, the latter in CO_2; in both tests a constant rate (1.120 lbs./sq. in. per minute) of loading was used.

Curves 3 and 4 (156,157) are for annealed electrolytic copper (arsenic, antimony, selenium, tellurium less than 0.05%; bismuth, 0.0005%) and for arsenical copper (arsenic, 1.2%) respectively, tested in air. Curve 5 gives the yield point for the electrolytic copper. Rate of loading was not constant nor given.

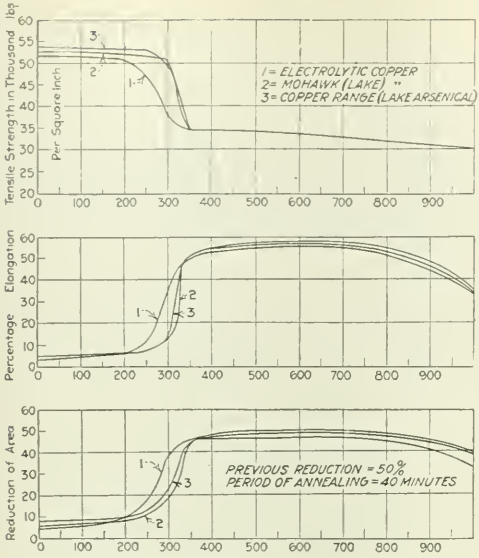
Curve 6 is for "pure" copper (159).

Huntington (156, 157) has carried out alternating stress tests on copper up to 500 deg. C. and finds that the number of alternations to failure decrease with the temperature of test in much the same manner as does the ultimate strength.

Guillet and Bernard (153) have carried out impact tests on copper up to 1000 deg., and find a linear decrease of the specific impact work required to bend the specimens (none of the test specimens fractured).

Heat Treatment of Copper; Effect on Physical Properties

Cold-worked copper is softened by annealing, the ultimate tensile strength being decreased and the ductility increased. The temperature range within which this softening takes place most rapidly is from 200 deg.



Tensile Strength in Thousand lbs. Per Square Inch

to 325 deg. C. for pure copper, reduced 66⅔ per cent (186, 197), but is markedly affected by two factors:

(1) Extent of previous cold reduction,

(2) Presence of impurities.

Fig. 19 shows the annealing characteristics of three commercial grades of copper, the same, of which the characteristics were described on page 193 and in Fig. 16, and of which the analyses were then given. It is noticed that the presence of arsenic raises the annealing range of the copper.

Impurities such as arsenic and silver raise the annealing temperature range of hard copper; oxygen lowers it. This is seen from the curves in Fig. 20.

The range of softening temperatures for copper is lower the greater the previous cold reduction. This is shown in the curves of Fig. 21.

Bardwell has studied the effect of annealing in raising the conductivity of hard drawn copper wire. His curves are given in Fig. 22.

The properties of copper are not affected by a rapid cooling after annealing or rolling as are steel and certain copper alloys. It is generally held that quenching copper in water after annealing produces a softer metal than if it were slowly cooled; there is, however, evidence both for and against this view.

Martens (140) found that two similar bars of copper, cold-worked and annealed, of which one (a) was quenched and (b) was slowly cooled, possessed the following properties:

	Tensile Strength		Elongation in 10 cm., per cent	Reduction of Area, per cent
	Lb./Sq. In.	Kg. mm.²		
(a)	30,900	21.7	47.1	57
(b)	30,800	21.6	51.8	60

Johnson (261) also finds that his specimen EE, Table IX, which was cooled slowly after hot rolling has a greater ductility than two specimens of similar composition which were quenched.

Impurities in Copper; Effect on Physical Properties

The various physical and other characteristics of copper are affected in quite varying degree by the presence of impurities. Most markedly sensitive are the electrical and probably also the thermal conductivities and the mechanical properties (particularly ductility), especially at high temperatures, to the presence of impurities. The melting (also boiling) point is changed by the presence of impurities; information concerning this is given by the equilibrium diagrams of these elements and copper. It has been noted that the magnetic susceptibility is very profoundly altered by the presence of slight amounts of iron. Otherwise the effect of impurities in the amounts ordinarily found in good commercial grades of copper have but little influence on it. The specific heat, for example, is an additive constant. Practically no data are now available concerning the effect of small amounts of impurities on the characteristics of copper other than those mentioned

FIG. 20. EFFECT OF IMPURITIES ON THE ANNEALING PROPERTIES OF COPPER (186)

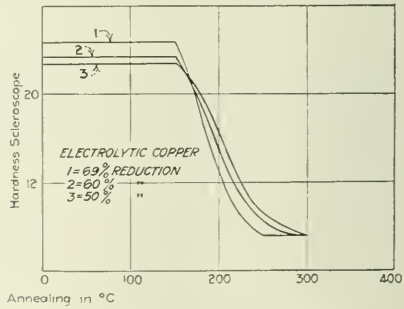

FIG. 21. EFFECT OF EXTENT OF PREVIOUS REDUCTION ON TEMPERATURE ANNEALING RANGE FOR COPPER (186)

1. Electrical Conductivity

Addicks (243) has investigated systematically the influence of impurities on the electrical conductivity of copper. He used high conductivity wire (99.5 to 101 per cent) in making up his alloy ingots; this was melted in a reducing atmosphere under charcoal with the added impurity. The ingot was cast in a heated iron mold, swaged down and drawn cold to No. 12 B. & S. gage. The wires were then all annealed by passing 110 amperes through them and tested. Fig. 23 gives a summary of the results of his tests. The presence of all of these impurities lowers the conductivity, arsenic, phosphorus and aluminium being particularly effective in this direction.

2. Mechanical and "Working" Properties

A great deal of investigation has been made of the effect of individual impurities on the mechanical properties of copper, not all of which has been conducted with a full recognition of the factors which must be considered in manufacturing conditions. A knowledge of the effect of an impurity in small amounts on the otherwise pure copper is undoubtedly valuable, but such copper is not a commercial product. From the practical viewpoint the effect of such impurities should always be considered in conjunction with that of the other usual impurities, principally oxygen. It is a fact that the effect, particularly of lead, antimony and bismuth, is most markedly altered by a variation of the presence of oxygen, arsenic, and other elements.

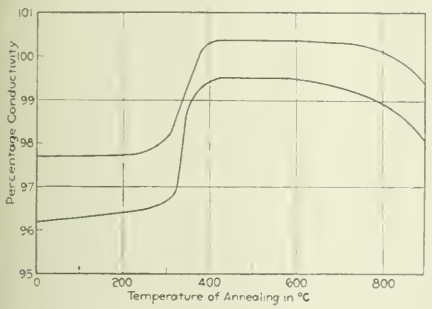

FIG. 22. EFFECT OF ANNEALING UPON THE ELECTRICAL CONDUCTIVITY OF HARD DRAWN COPPER (185)

	% Oxygen	% Arsenic + Antimony	% Copper + Silver
Material 1..	0.070	0.0038	99.92
Material 2..	0.046	0.0038	99.945

Previous reduction not given.

In considering the effect of individual elements a knowledge of the equilibrium diagrams of the binary alloys of these elements with copper is really necessary. Reference is made to these in the bibliography. The impurities to be considered may be classified according to whether moderate amounts of it are soluble as a solid solution in copper (manganese, nickel, zinc, tin, aluminium, etc.) or whether the impurity is but slightly soluble in the copper (bismuth, lead, etc.). It is then found in general that impurities of the former class harden copper, diminish its ductility, but increase its toughness and better its rolling and working properties, whereas those of the latter class do not harden the copper, but diminish both the ductility and the toughness and are quite injurious as regards the hot-working properties. The reason for this latter effect is to be found in the presence of the impurity as segregated particles or films of low melting point (300 to 500 deg. C.). The action of arsenic and oxygen is more complex.

Aluminium

The equilibrium of copper-aluminium alloys has been studied by Carpenter and Edwards (196), Curry (197), and Gwyer (198). Copper takes up approximately 9 per cent of aluminium in solid solution.

Some results of Johnson (261), Table IX, indicate the effect of this metal on the properties of copper.

Antimony

The constitution of the copper-antimony alloys has been studied by Hiorns (200) and Baikoff (199). From 2 to 3 per cent of antimony as Cu Sb are held in solid solution by copper.

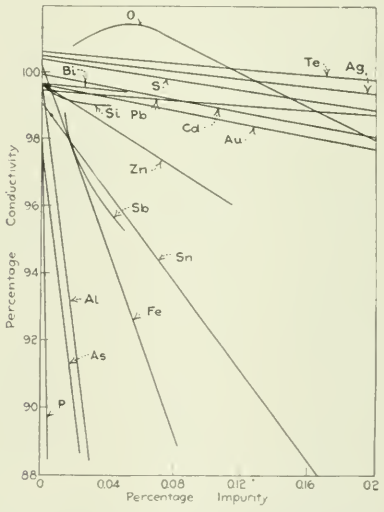

FIG. 23. EFFECT OF IMPURITIES ON THE ELECTRICAL CONDUCTIVITY OF COPPER (ADDICKS) (243)

Johnson (259) has studied the effect of antimony versus the mechanical and working properties of "tough-pitch" copper. He drew the following conclusions from his results, which are summarized in Table V:

"(1) Antimony up to 0.5 per cent has no detrimental influence on the hot-forging qualities of 'tough-pitch' copper free from other impurities. It is even possible to forge copper containing 1 per cent antimony if sufficient oxygen be present.

"(2) In copper which has been overpoled, antimony tends to mitigate the phenomenon of 'spewing' during solidification.

"(3) 'Tough-pitch arsenical copper (0.4 per cent arsenic) is slightly hardened after hot-rolling by the presence of antimony (0.2 per cent), but otherwise its mechanical properties are slightly improved.

"(4) The mechanical properties of 'tough-pitch' pure copper after rolling and annealing are but slightly altered by small additions of antimony. The tensile strength is slightly raised (5 per cent), and the elongation lowered (10 per cent). The slight gain in toughness is probably traceable to the greater soundness of the ingot.

"(5) With regard to the structural condition of antimony in 'tough-pitch' copper, it exists in two forms:

"(a) Partly in solid solution (as Cu_3Sb).
"(b) Partly as an insoluble compound with oxygen (slate-colored 'oxidules').
"Oxygen in excess exists as Cu_2O. The latter, together with the antimony oxidules, form a ternary eutectic with the solid solution."

TABLE V—INFLUENCE OF ANTIMONY ON "TOUGH-PITCH" COPPER, JOHNSON (259)

Specimens taken from rods rolled at red heat (900° C.) from 1¼-in. square ingots; rod rolled in 6 passes to ½ in., finished at dull red heat, annealed by raising to a bright red heat, quenched in pickling bath, rolled cold to 5/16 in., and straightened by drawing once through a die. All ingots were tough-pitch, with level surface; they all rolled perfectly. The copper used was the purest electrolytic (Viviao & Sons, Swansea).

No. of Ingot	Chemical Composition			Rods as Rolled			Rods as Annealed		
	Oxygen, per Cent	Arsenic, per Cent	Antimony, per Cent	Tensile Strength, Lb./Sq. In.	Elongation in 3 In., per Cent	No. Alternations to Rupture, Arnold Test	Tensile Strength, Lb./Sq. In.	Elongation in 3 In., per Cent	No. Alternations to Rupture, Arnold Test
RR	0.05	...	...	44,400	14.7	118	32,200	51.3	244
A3	0.058	...	0.2	43,700	13.0	136	31,900	43.3	210
A2	0.054	...	0.29	43,600	16.7	116	33,500	46.0	268
AA2	0.063	...	0.3	43,800	13.0	118	32,800	48.3	258
AA1	0.33	...	0.49	45,500	6.0	49	34,000	44.7	138
A	0.065	0.36	0.2	45,200	15.3	119	33,500	48.7	258

All of the ingots given in the table rolled well, hot; ingot A1, containing antimony, 0.5 and O_2 0.02 (overpoled), was red-short and was removed from the rolls at the third pass; samples of 5/8-in. rods were rolled cold after annealing into strips ⅛ in. thick. Rods RR, A, A2 and AA2 showed no edge cracking; AA1 showed edge cracking when a thickness of 3/16 in. had been reached.

There is much further information of a special nature in this paper and the discussion on it which will interest those desiring more complete information on this subject.

The earlier investigators of this subject were Hampe (253), Hiorns (256), Greaves (252), T. Johnson (264), Lewis (269), Archbutt (244). Hampe finds that copper with 0.53 per cent antimony can be drawn into wire, and with 1 per cent antimony is red-short. Hiorne finds that antimony (0.2 per cent) when added to copper containing lead (0.2 per cent) diminishes the brittleness caused by the lead.

Baucke (246) has determined the effect of antimony on the toughness (specific impact work necessary for fracture) of copper; see Table X.

ARSENIC

The constitution of the copper-arsenic alloys has been studied by Friedrichs (201) and by Bengough and Hill (202).

A compound Cu_3As is formed which is partly soluble in solid copper; the exact limit of solubility has not been determined; it lies probably between 1 and 3 per cent arsenic (i.e., copper will take up in solid homogeneous solution that quantity of arsenic as Cu_3As).

Next to oxygen this is probably the most important impurity occurring in copper. Lewis (268) and Bengough and Hill (247) have studied its effect on the mechanical properties of rolled copper; their results are summarized in Tables VI and VII.

Bengough and Hill summarize their mechanical tests as follows:

"(1) Arsenic in small quantities tends to increase the maximum stress without affecting appreciably the ductility of these alloys.
"(2) It increases their resistance to reducing gases at high temperatures.
"(3) Alloys with low percentages of arsenic tend to be unhomogeneous, but with increase in the arsenic this ceases to be apparent.
"(4) In ordinary oxidizing atmospheres no heat treatment (for three hours or less) short of an approximation to fusion seriously affects the properties of these alloys. The only result of annealing is to render the bars slightly more homogeneous and to lower the yield-point somewhat. This statement, however, does not apply to annealing temperatures in the neighborhood of 1000° C.
"(5) Alloys containing less than 1 per cent of arsenic are ruined by the action of reducing gases for three hours at 700° C. or above it; in some cases the action is apparent at 600° C.
"(6) The yield-points of these alloys are somewhat variable and unsatisfactory.

TABLE VI

Influence of arsenic upon the mechanical properties (tensile test) of rolled copper (Lewis, 268). Specimens were cast, rolled hot to ½ in. diameter and quenched.

Arsenic, per Cent	Tensile Strength, Lb./Sq. In.	Elastic Limit, Lb./Sq. In.	Elongation per Cent

[1]No trace found of lead, tin, or iron.
[2]Results are average of two tests.

According to these investigators arsenic in amounts up to 1.9 per cent causes, therefore, neither hot nor cold-shortness when, as usual, copper oxide is present, i.e., in tough-pitch copper. It seems that the presence of oxide affects the influence which arsenic exerts on copper. Roberts-Austen (275) find that 1 per cent arsenic begins to cause red-shortness in oxide-free copper. Jolibois and Thomas (262) state that 0.4 per cent arsenic causes cold-shortness in pure copper, whereas 0.4 per cent $As_2O_5.Cu_2O$ does not.

Baucke has studied the effect of arsenic on the toughness of copper; see Table X.

"Arsenical" copper such as is used commercially for copper which must resist high temperatures, in locomotive fire boxes, etc., contains from 0.1 to 0.4 per cent of arsenic.

BISMUTH

The constitution of the copper-bismuth alloys has been studied by Jeriomin (204), Portevin (203) and others. The amount of bismuth taken up by copper in solid solution is practically zero; it has never been accurately determined.

Johnson (261) has investigated the effect of small amounts of bismuth on the tensile properties, ductility and malleability of tough pitch copper. His results are summarized in Table IX. His conclusions are:

"The effect of bismuth on the mechanical properties of 'tough' arsenical copper which has been rolled is not

serious up to 0.1 per cent; but no commercial arsenical copper could be regarded as fit for working at a red heat which contained so much bismuth. With 0.02 per cent, although the hot-working properties would be noticeably worse than if no bismuth were present, the copper would not be ruined. Any crude copper containing over 0.01 per cent bismuth should be regarded with suspicion, since the copper might contain traces of other impurities, e.g. nickel, which, while intensifying the injurious effect of bismuth, would hinder the corrective action of arsenic."

Johnson also concludes that an explanation of the less intense effect of bismuth on the hot-rolling properties of oxygen-bearing copper is due to its presence therein as Bi_2O_3 or combination thereof as isolated particles, whereas in overpoled or oxygen-free copper the bismuth is present as films of metallic bismuth, which, owing to its low melting point, destroys the cohesion of the mass at high temperatures.

Other investigators of this subject have been Roberts-Austen (275), Hampe (253), E. A. Lewis (269), Arnold and Jefferson (245). Roberts-Austen made oxygen-free, bismuth-bearing copper alloys which could not be worked at all over 0.1 per cent bismuth. Lewis comes to practically the same conclusions as does Johnson regarding allowable bismuth limits and shows that whereas arsenic corrects the ill effects of bismuth, they are intensified by manganese, tin, aluminium, etc.

IRON

The constitution of the alloys of copper with iron has been studied by Ruer and Fick (211), Sahmen (210), and others. Copper will take up 2 or 3 per cent of iron in solid solution. Within those limits iron hardens copper and diminishes its ductility.

LEAD

The constitution of the copper-lead alloys has been studied by Friedrich and Leroux (212), Heycock and Neville (213), and others. The amount of lead which copper will hold in solid solution is very small, probably much less than 0.1 per cent. No systematic study has been made of the effects of lead on the mechanical properties. Its effect on the working properties at high temperatures is dependent on the amount of arsenic or Cu_2O present; 0.1 per cent of lead would render pure copper unworkable, whereas with 0.3 or 0.4 per cent arsenic such a percentage of lead is not out of the question.

Archbutt (244) was able to forge oxide-free copper ingots containing 0.05 per cent lead and those containing 0.1 per cent lead and 0.4 per cent arsenic without cracking of the ingots.

Johnson (259) states that the mechanical properties of arsenical copper at ordinary temperatures are but slightly affected by the addition of lead. Rods prepared by him (see Table V for method of preparation) containing oxygen, 0.023; arsenic, 0.39; lead, 0.18 per cent, showed the following properties:

	Tensile Strength, Lb. /Sq. In.	Elongation in 3 In., per Cent	Alternations to Rupture Arnold's Test
As rolled	41,200	17.3	169
As annealed	32,900	53.3	238
Original electrolytic copper			
As rolled	41,400	14 7	118
As annealed	32,000	51.3	244

The ingot of this leaded copper rolled well (see Table V for description of rolling), whereas one containing 0.012 per cent oxygen, 0.38 per cent arsenic, and 0.35 per cent lead cracked at first pass.

MANGANESE

The constitution of the alloys of copper and manganese is discussed by Sahmen (219), Schemtuny, Urasow and Rykowskow (218), and others. Copper and manganese form a continuous series of solid solutions.

Münker (273) gives results of tests of alloys of copper and manganese (see Table VIII), from which it is seen that manganese in small amounts hardens copper and diminishes its ductility.

Baucke has studied the effect of manganese on the toughness of copper (see Table X).

TABLE VIII[1]—EFFECT OF SMALL ADDITIONS OF MANGANESE, PHOSPHORUS, AND TIN ON THE MECHANICAL PROPERTIES OF COPPER (MUENKER, 273)

[1]The alloys were made under commercial conditions with B. E. R., copper and additions of phosphor-copper, tin-copper, and mangan-copper. The cast slabs were first hot rolled and then finished cold. Samples were annealed at 500° C. and either quenched or slowly cooled. The tensile tests were carried out on strips 3 mm. thick, 15 mm. wide, of a test length of 11.3 $\sqrt{\text{cross section}}$, or about 75 mm. The Brinell tests were made with a load of 500 kg. and a ball of 5 mm. diameter.

[2]The phosphorus alloys were otherwise as pure as the original B. E. R. copper; the manganese and tin alloys contained also from 0.012 to 0.020 per cent of phosphorus.

NICKEL

The constitution of the nickel-copper alloys has been studied by Guertler and Tammann (220), Tafel (222), and others. The two metals form a continuous series of solid solutions.

Small additions of nickel harden copper and diminish the ductility slightly, but apparently increase its toughness; see Table X (Baucke).

(To be continued)

Aluminium in 1917. — The value of primary aluminium made in the United States in 1917, according to the Geological Survey, was $45,882,000, an increase of $11,982,000 over the value of that made in 1916. This increase appears to be due chiefly to an increase in the quantity of metal produced.

Fats and Fatty Acids from Petroleum

By Robert J. Moore and Gustav Egloff

In considering the subject of the transformation of one class of oils into another of greater economic value, it seems advisable, as an introduction, to review the main classes into which "oily" matter in general may be divided. These classifications may be made first, through their physical properties and occurrence, and, second, by their chemical structure.

The term oil includes a vast number of substances, both natural and artificial, possessing widely different physical properties and chemical structure. All substances included in this term are practically insoluble in water, possess a characteristic greasy touch and have a low surface tension. This latter property forms the basis of the well-known definition that "an oil is a substance which, when dropped on paper, forms a translucent spot which is not removable by washing with water."

By the action of boiling alkali solutions we are able to separate oils into two large groups. One group splitting into fatty acids and free glycerine, a process which is called saponification, while the other group is not affected. The saponifiable oils are divided into animal oils and vegetable oils, depending on their origin. The vegetable oils are further classified according to physical properties into drying, semi-drying and non-drying oils and solid fats. The unsaponifiable oils are subdivided into mineral oils, which constitute the vast amount of petroleum and shale oils; rosin oils, tar oils and ethereal oils. The complete general system of classification is shown in the accompanying diagram.[1]

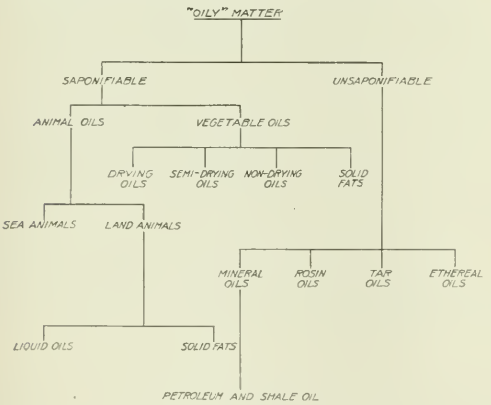

FIG. 1. CLASSIFICATION OF OILS

The naturally occurring animal and vegetable fats and oils consist essentially of mixtures of glycerides. Fats and glycerol esters of fatty acids when hydrolysed yield free glycerol and fatty acid, thus:

$$\underset{\text{stearin (glyceryltristearate)}}{C_3H_5(C_{18}H_{35}O_2)_3} + 3H_2O \leftrightarrow \underset{\text{glycerol}}{C_3H_5(OH)_3} + 3\underset{\text{stearic acid}}{C_{18}H_{36}O_2}$$

Since the glycerol radical is common to all, the nature of the fat depends upon the acid with which the glycerol is combined. These acids may be of the following groups:

[1] Southcombe's "Chemistry of the Oil Industries."

Series $C_nH_{2n}O_2$

Under this series occur

Butyric acid $C_4H_8O_2$ in butter.

Caproic acid $C_6H_{12}O_2$ in goat and cow butter, cocoanut fat.

Caprylic acid $C_8H_{16}O_2$ in human fat, butter, cocoanut oil.

Palmitic acid $C_{16}H_{32}O_2$ in many fats and oils.

Stearic acid $C_{18}H_{36}O_2$ in most fats.

Series $C_nH_{2n-2}O_2$.

Oleic acid $C_{18}H_{34}O_2$ is present in nearly all fats and fatty oils.

Other series, such as $C_nH_{2n-4}O_2$, $C_nH_{2n-6}O_2$ and $C_nH_{2n-8}O_2$, are found as glycerides in some of the fats; for example, linoleic acid ($C_{18}H_{32}O_2$) and linolenic acid ($C_{18}H_{30}O_2$) are found in linseed oil and other drying oils.

While small percentages of these free fatty acids may occur in the oils and fats, the main constituent is the glycerol ester. Thus we have tributyrin in butter fat, tripalmitin in palm oil, triolein and tristearin in most fats and oils.

The Mineral Oils

The chief division under the second general group of oils called unsaponifiable is the mineral oil division, embracing all petroleum and shale oils, and is the division to which we will, for the present, confine our attention. Petroleum oils are found widely disseminated in nature, the most important fields being the California, Texas, Mid-Continent, and the Eastern fields in the United States; the Russian, Galician, Roumanian and Italian in Europe, and the Mexican fields, which are now being rapidly developed. There are, besides these many productive districts in Asia and the East Indies. The world's production[2] for 1915 was 427,695,347 barrels, of which the United States produced 65 per cent. Russia ranks next in production and Mexico third. The total output for 1916 amounted to 460,639,000 barrels.

The hydrocarbons composing petroleums differ widely in nature. The Eastern oils are almost entirely of the paraffin or saturated series, the Mid-Continent semi-asphaltic, the California and Texas oils contain compounds mostly of the asphaltic type, while the Russian and Galician fields are mainly naphthenic.

The accompanying Table I contains hydrocarbons, homologs of which have been isolated in crude oil from the various fields:

TABLE I

Name	Formula	Occurrence
Paraffins	C_nH_{2n+2}	Pennsylvania; some in other American oils, only small percent in Russia.
Olefins	C_nH_{2n}	In Canadian and California oils. To small extent in Pennsylvania and other oils.
Naphthenes	C_nH_{2n}	Predominate in Russian oils. Franklin oils of Pennsylvania. Found to small extent in other crudes.
Asphaltic	C_nH_{2n-4}	In Texas and California oil.
Acetylenes	C_nH_{2n-2}	Baku oils in small amount.
Benzenes	C_nH_{2n-6}	To some extent in most crudes fair percent in California oils.
Phenylethenes	C_nH_{2n-8}	Slight extent; uncertain.
Phenylethines	C_nH_{2n-10}	Slight extent; uncertain.
Naphthalenes	C_nH_{2n-12}	Slight amounts in Rangoon oils.

The hydrocarbons which we are mainly interested in for present purposes are the paraffins, the naphthenes and the olefins. Our interest from now on will be directed to the many methods that have been offered for preparing fats and fatty acids from the above type hydrocarbons in petroleum oils.

[2] Petroleum in 1915, J. D. Northrop.

Conversion of Petroleum Hydrocarbons to Fats and Fatty Acids

The past work on this subject, all of which is of rather recent date, may be divided for simplification of narrative into four different methods:

1.—Through halogenation of aliphatic hydrocarbons.
2.—By way of Grignard's reaction.
3.—By way of naphthenes.
4.—Through direct oxidation of paraffins or olefins.

1. THROUGH HALOGENATION

In considering the problem of forming fatty acids from paraffins, the simplest method that might appeal to us is the conversion of a methyl group, of a boiling point in the neighborhood of 300 deg. C. into the carboxyl group. Thus hexadecane $CH_3(CH_2)_{14}CH_3$ boiling point 287.5 deg. C. might be oxidized to $C_{15}H_{31}COOH$ (palmitic acid) by the mere conversion of one methyl into a carboxyl group. The introduction of halogen into the paraffin seems to offer the most feasible first step in this reaction, and has been the subject of many patents. The Badische Anilin & Soda Fabrik[3] produce halogen derivatives of the paraffin series by mixing the oil and the halogen in the dark, vaporizing and subjecting the mixture to the action of the silent electric discharge. Halogenation takes place immediately. Pfeifer & Szarvasy[4] also use the silent discharge to effect the reaction, while Ellis[5] uses ultraviolet light for the halogenation of various hydrocarbons.

The writers, in a series of preliminary experiments, passed vaporized kerosene and chlorine, after heating, into an electrical silent discharge field of high potential, adding carbon dioxide at the same time. The experiments, though preliminary in nature, showed an increased specific gravity in the oil and a tendency to emulsify with sodium hydroxide solution. Indications are that a certain amount of fatty acids are formed under these conditions, the data of which will be given in a later communication. Further work along these lines is in progress.

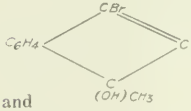
H. Strauss[6] produces monochlor compounds of the higher hydrocarbons of petroleum by treating in the gas phase, under reduced pressure, with chlorine. Information is lacking as to just how oxidation is effected, whether directly to acids or by way of alcohols and aldehydes.

As in most work on commercial problems of this sort, very little is stated as to details and yields. It is, however, quite possible to prepare fatty acids by this method, although its economic success probably depends upon further research.

2. BY GRIGNARD'S REACTION[7]

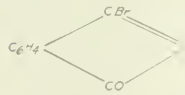
Zelinski[8] found that the reaction between magnesium and chlorinated hydrocarbons may be rendered complete by the addition of a catalytic agent such as iodine, aluminium halides or hydrochloric acid. He chlorinated the petroleum, dissolved it in anhydrous ether and treated this mixture with metallic magnesium and the catalyst. Subsequently, when cold, a current of carbon dioxide was passed through, decomposing the complex magnesium compound thus obtained. The fatty acids were then liberated from the magnesium compounds by dilute acid. Zelinski claims for this method a yield of 60 per cent of the theoretical. Pentane yielded isohexoic acid. A naphthene fraction (80-82 deg. C.) yielded cyclohexanecarboxylic acid, while a naphthene (71-79 deg. C.) yielded heptoic, methylcyclopentanecarboxylic and cyclohexanecarboxylic acids. He succeeded in synthesizing acids containing up to ten carbon atoms in the molecule, and in preparing a di- and tri-octin from an acid of the Formula $C_nH_{2n}O_2$ belonging to the same group as oleic acid, by heating the fatty acid with glycerine to 250 deg. C. While it is true that acids with more than ten carbon atoms show an essentially different action chemically from that of the lower fatty acids, still, if the lower acids may be so readily prepared, the synthesis of the higher acids is merely a matter of degree, which further research should make possible. Moreover, hydrogenation of unsaturation of unsaturated acids and bromine substitution is being rapidly improved, as a glance at recent patent literature will show, and the transformation to higher or lower acids is becoming more and more a commercial practice. The Vereinigte Chem. Werke of Charlottenberg has made a special problem of hydrogenation and has conducted it on an enormous scale, using a temperature of 100 deg. C. with 2 to 3 atmospheres pressure and 0.00002 parts of palladium chloride in an alkali as catalyst. In 1914 they predicted[9] that the synthetic production of fatty acids and fats from hydrocarbons by the process of Zelinski[10] was commercially feasible, but that the cost of the product was then still too high. Since the beginning of the war nothing authoritative has been published as to the German industries, *but it is not improbable that Germany to-day is supplying a large part of her fats from synthetic production.*

Bjelous[11] uses the Grignard reaction for the production of alcohols from olefins. This reaction is also used by Simmonis and Kirschten,[12] who have isolated and determined the composition of many halide compounds which may readily yield acids. Among these we find



1.2-dibrom-3-methyl indenol.

and



1-brom-2-iodine-indenol.

3. BY WAY OF NAPHTHENES

Naphthenes form the bulk of the Russian and Galician oils, and much experimenting has been done by Russian chemists on cracking and other forms of treatment of these hydrocarbons. Many investigators have

[3]Eng. Pat. 5125, 1912.
[4]U. S. Pat. 1012, 149.
[5]U. S. Pat. 1146, 142.
[6]Germ. Pat. 267, 204 (1912).
[7]Grignard's reaction employs metallic magnesium, the alkyl halide and anhydrous ether. The magnesium dissolves forming an alkyl magnesium halide as CH_3MgBr. When CO_2 is passed through this the addition product $CH_3CO.OMgBr$ is formed which upon hydrolysis yields the acid, thus:

$$CH_3CO.OMgBr + H_2O \rightarrow CH_3COOH + Mg(OH)Br$$

For further consideration of this reaction see Hewitt and Steinberg, *Proc.* Chem. Soc., 1912, 140; Zaretwitinoff, *Ber.*, 1912, 2384; Hibbert, *Proc.* Chem. Soc., 1915, 15; Simmonis and Kirschten, *Ber.*, 1912, 568.
[8]Ger. Pat. 151, 880; Ber. 1912, 2687 (Chem. Zeit. Rep. 1909, 631.

[9]See M. Colletas, *Mit. Gross.* 7, 4153, 1914
[10]Loc. cit.
[11]*Ber.*, 1912, 627
[12]*Berichte*, 1912, 568

found that a certain amount of oxygen is present in these oils as naphthenic acids. Markownikoff has isolated octanaphthenic acid,

and hexa, hepta, nono and deka naphthenic acids have been obtained from the alkali washings. E. Pyhalla[15] finds these acids present to about 0.9 per cent in Russian oils and suggests that they be neutralized with caustic soda, before refining, and made into soaps. He finds also[16] that the fraction of Baku petroleum boiling between 98 deg. and 106 deg. C. yields up to 20 per cent of its weight of adipic acid, which, by way of its amide, can be converted into butadiene and synthetic butadiene rubber. Pyhalla suggests that if these butadiene hydrocarbons could be isolated from the petroleum by a simple, direct process, this route to synthetic rubber would be a good one.

The production of glycerides from these free naphthenic acids is readily accomplished, but the resulting fat shows characteristic differences in properties from natural fats. The naphthenic fats are heavier than water (specific gravity 1.008 at 15 deg. C.), and tend to form plastic masses. This latter property has led to many patents for the production of India rubber substitutes, one of the most promising of which is Chercheffsky's.[15]

Naphthenes lend themselves to the Grignard reaction as readily as paraffins and have been used in Zelinsky's experiments.

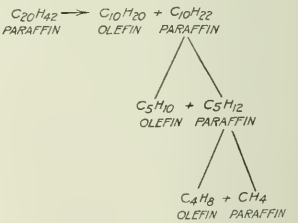
4. DIRECT OXIDATION OF PARAFFINS AND OLEFINS

Probably the most direct method of synthesizing the fats, and the method which, at the same time, seems to be of commercial significance, is the oxidation of paraffins and olefins to acids. This may be accomplished by air or other oxidizing agents and by way of alcohols or aldehydes. That the oxidation of even so inert an oil as paraffin vaseline can be made to yield acids is shown by the work of Benedix.[18] He intimately mixes the oil, in the presence of water, with sodium peroxide or hydrogen peroxide, diluted with alkalies and alkaline salts. After being stirred for some time, the mass thickens and part of the hydrocarbon is oxidized to acids, which combine with the alkali present to form soaps. The reaction is promoted by the addition of alcohol, and by heating to about 80 deg. C. under pressure. The resulting product is in the form of a soft paste, which "may be readily distributed in water and possesses great detergent power."

Schultz[17] by passing a rapid current of air through burning paraffin oil or hot lubricants obtained chiefly aldehydes, carbon monoxide and a small quantity of acids, but his work was rather crude and inadequate. Two recent patents,[18] couched in identical terms, are highly promising. In these experiments paraffin wax, in a molten condition, is treated with a blast of air or oxygen for a prolonged period, at a temperature of 100 deg. C. to 120 deg. C. The color changes to light red, light yellow and finally to a deep yellow. At this stage about 70 per cent of the wax has been converted into fatty acids, and a small quantity of alcohols, formaldehyde and the like. The different products are separated by distillation and the unchanged wax re-treated. Mercuric oxide or wax that has already been treated may be used as catalysts. By this process it seems possible to convert some 80 to 90 per cent of paraffin wax into fatty acids. The significance of this is readily appreciated. Moreover, Gray's experiments[19] seem to offer almost equally as favorable results. Gray blows air through the oil, at the same time subjecting to the actinic rays of ultraviolet light. With the assistance of heat (90-175 deg. C.), pressure and catalysts, such as finely divided metals, he converts part of the oil into fatty acids. With a lower temperature this process is used for the deblooming of certain paraffin oils.

Both of the above patents treat paraffin oils, which are saturated compounds and decidedly stable. It would seem advisable, therefore, to use as a starting material olefins which are unsaturated in structure and much more readily oxidized to acids. Olefins are not found to any considerable extent in natural petroleums, but a glance at the literature will show that they are readily obtained from petroleums in many ways.

Thorpe and Young[20] found that paraffins on being distilled under pressure at high temperature are decomposed into liquid hydrocarbons of the ethylene and methane series. Among the former were found up to nonylene. The general type of the so-called cracking reaction is as follows:



Gawalowski[21] finds that paraffins on prolonged heating alone yield gaseous and liquid products of the ethylene and acetylene series. Armstrong and Miller,[22] in investigating the by-products from the manufacture of Pintsch gas, found a high percentage of olefins up to crotonylene. The tars recovered from cracking Russian petroleum were found[23] to contain large amounts of hexylene and heptylene. Egloff and Moore[24] were able to prepare from 4 per cent to 95 per cent of olefin in the gasoline cuts from cracked paraffin oils by varying temperature and duration of reaction. In general, "high temperature of cracking makes for high unsaturation."[25]

Since the olefins are so readily obtainable from paraffin oils, and since they are readily oxidized, they offer an inviting field for experimentation. Greenstreet's[26] work upon this subject has led to the production of alcohol and fatty acids. He passes mineral oils mixed with steam through long coils of pipe heated to a cherry red

thus cracking to olefins. The olefins are then oxidized and the products separated by fractional distillation. Oxidation may be effected by treatment with sulphuric acid to convert to the corresponding sulphuric ethers and then converted by water to alcohols. Or the olefins may be oxidized directly to aldehydes and acids by permanganate or chromic acid solution.

It is apparent from the foregoing work that fatty acids of various types may be prepared from petroleum hydrocarbons, in commercial quantities. Since, therefore, it is practicable to prepare certain fatty acids from petroleum, the question of changing to higher or lower acids, or from unsaturated to saturated acids, is being successfully answered in many recent patents, notably those of C. Ellis. Hydrogenation may alter acids as follows:

$$\underset{\text{linoleic acid}}{C_{17}H_{31}.COOH} + 2H \rightarrow \underset{\text{oleic acid}}{C_{17}H_{33}.COOH} - 2H \rightarrow \underset{\text{stearic acid}}{C_{17}H_{35}.COOH}$$

The carbon chain of fatty acids may also be broken down in many ways. A new method of accomplishing this is brought forth by Levene and West.[27] It consists in transforming the high fatty acid into its alpha-hydroxy-acid, which is then oxidized in hot methyl acetate with potassium permanganate. The potassium salt of the new acid is insoluble in the methyl acetate and precipitates, together with manganese dioxide, from which it is separated by hot alcohol. By this method Levene and West were able to obtain from stearic acid 80 to 85 per cent of margaric acid. Lignoceric and pentadecyclic acids were also formed from cerebronic and palmitic acids respectively.

It seems feasible, therefore, to prepare a fatty acid from petroleum oils that will have the same composition as an acid derived from natural fats. Or the acid formed may be so shifted by hydrogenation, or by breaking down the carbon chain, as described above, so as to finally produce the acids as found in natural fats.

The fats themselves, which are the glycerol esters of these fatty acids, may be readily prepared on a large scale by combination with glycerol. For this purpose may be employed such methods as heating with glycerol to 220 deg. C. under pressure,[28] by the action of Twitchell's reagent (sulpho-aromatic compound) on the acid and glycerol,[29] or by the action of enzymes.

The importance of the conservation and production of fats in this catastrophic period in world history can be gleaned from the following shortage and further developing shortage of livestock throughout the world.[30] The German army has taken from Belgium and France 1,800,000 head, and the herds of France had already decreased a year ago 16.6 per cent. To-day France is producing only one gallon of milk where two and one-half were produced before the war. The Allies, excepting the United States, have reduced their stock of cattle, sheep and hogs to the extent of 33,000,000 head since 1914 and the world stock to the extent of 115,000,000 head. According to Mr. Hoover, the per cent of hogs slaughtered in the fiscal year 1916-1917 was 96, while 86 per cent was slaughtered in 1916, and furthermore the average weight had fallen from 219 to 211 pounds per hog. In short, at the present time we have approximately 5,000,000 hogs less than our normal supply. The supply of cattle and sheep has been similarly affected hence it behooves us to search for commercial synthetic methods for the production of fats.

The foregoing work shows the extent to which the synthetic production of fats and fatty acids from hydrocarbons present in petroleum oil has been successful. Further work along the lines indicated by the writers is being carried on and will be reported upon in a later paper. It may be stated, however, that the collective work shows a considerable degree of success, and that "fats and fatty acids from petroleum" is more than an empty phrase.

Another Source of Toluol

Every possible source of toluol is being investigated by the War Department. It was brought out at the meeting of the Technical Association of the Pulp and Paper Industry on Feb. 6 and 7 in New York that toluol can be produced from spruce turpentine, which is an oil formed during the cooking of the chips in sulphite digesters, which escapes with the steam in the blowing-out process, and is generally allowed to go to waste, though processes of recovering this crude form of turpentine are carried out in a few mills.

A representative of the War Department, Milo R. Maltbie, was present at the meeting on Feb. 7 and explained the need for toluol and stated that it was understood that 300,000 gallons could be obtained from the mills in the United States at very little expense to the mills. He pointed out that it was a patriotic duty for all the mills to install the apparatus to recover this spruce turpentine and ship it to a central refining plant if the War Department finds it desirable after its investigation. A committee of the Technical Association was appointed to co-operate with the War Department in ascertaining the supplies of spruce turpentine that are available for toluol manufacture.

While the total quantity of toluol as estimated by Mr. Maltbie is not large, considering that he stated that he had put 3,000,000 gallons under contract during the last six weeks, still every available gallon helps and all sources must be developed.

Domestic Tin Production.—A report by Adolph Knopf of the Geological Survey gives the production of metallic tin of domestic origin in 1916 as 140 short tons. The ore was derived almost wholly from Alaska. The bulk of the concentrate was shipped to Singapore, but part was sent to the tin-smelting plant of the A. S. & R. Co., at Perth Amboy, N. J. The total importation was 74,619 tons and tin recovered from drosses 17,400 tons. Nevada, the Carolina tin belt and the Black Hills of South Dakota have been prospected with no definite production as yet announced. The production of tin (mostly from Bolivian concentrate) at Perth Amboy in 1917 was about 6000 tons. It is expected to be increased in 1918 to 10,000 tons. The National Lead Company's new plant is also producing tin, but actual figures for 1917 are not yet available. The production of this American tin has helped considerably at a time when foreign tin has been hard to obtain.

A Bibliography of Alloys

Binary, Ternary and Quaternary Systems Whose Equilibria Have Been Investigated

BY CLARENCE ESTES

IN A PREVIOUS article[1] the writer gave a bibliography of the binary, ternary and quaternary systems of alloys whose equilibria had been investigated and published in *Chemical Abstracts* to Jan. 1, 1917, and the more important investigations published prior to the publication of that magazine.

The following bibliography is to supplement the original article. It includes the articles on the equilibrium system of alloys, abstracted and published in *Chemical Abstracts* from Jan. 1, 1917, to Jan. 1, 1918.

The number preceding a system refers to the list of references in the original article.
